

REST Web Services

32

Objectives

In this chapter you will learn:

- What a web service is.
- How to publish and consume web services in NetBeans.
- How XML, JSON, XML-Based Simple Object Access Protocol (SOAP) and Representational State Transfer (REST) Architecture enable Java web services.
- How to create client desktop and web applications that consume web services.
- How to use session tracking in web services to maintain client state information.
- How to connect to databases from web services.
- How to pass objects of user-defined types to and return them from a web service.

Outline

- 32.1** Introduction
32.2 Web Service Basics
32.3 Simple Object Access Protocol (SOAP)
32.4 Representational State Transfer (REST)
32.5 JavaScript Object Notation (JSON)
32.6 Publishing and Consuming SOAP-Based Web Services
- 32.6.1 Creating a Web Application Project and Adding a Web Service Class in NetBeans
 - 32.6.2 Defining the `WelcomeSOAP` Web Service in NetBeans
 - 32.6.3 Publishing the `WelcomeSOAP` Web Service from NetBeans
 - 32.6.4 Testing the `WelcomeSOAP` Web Service with GlassFish Application Server's Tester Web Page
 - 32.6.5 Describing a Web Service with the Web Service Description Language (WSDL)
 - 32.6.6 Creating a Client to Consume the `WelcomeSOAP` Web Service
 - 32.6.7 Consuming the `WelcomeSOAP` Web Service
- 32.7** Publishing and Consuming REST-Based XML Web Services
- 32.7.1 Creating a REST-Based XML Web Service
 - 32.7.2 Consuming a REST-Based XML Web Service

- 32.8** Publishing and Consuming REST-Based JSON Web Services
- 32.8.1 Creating a REST-Based JSON Web Service
 - 32.8.2 Consuming a REST-Based JSON Web Service
- 32.9** Session Tracking in a SOAP Web Service
- 32.9.1 Creating a `Blackjack` Web Service
 - 32.9.2 Consuming the `Blackjack` Web Service
- 32.10** Consuming a Database-Driven SOAP Web Service
- 32.10.1 Creating the `Reservation` Database
 - 32.10.2 Creating a Web Application to Interact with the `Reservation` Service
- 32.11** Equation Generator: Returning User-Defined Types
- 32.11.1 Creating the `Equation-GeneratorXML` Web Service
 - 32.11.2 Consuming the `Equation-GeneratorXML` Web Service
 - 32.11.3 Creating the `Equation-GeneratorJSON` Web Service
 - 32.11.4 Consuming the `Equation-GeneratorJSON` Web Service
- 32.12** Wrap-Up

[Summary](#) | [Self-Review Exercises](#) | [Answers to Self-Review Exercises](#) | [Exercises](#) | [Making a Difference](#)

32.1 Introduction

This chapter introduces web services, which promote software portability and reusability in applications that operate over the Internet. A **web service** is a software component stored on one computer that can be accessed by an application (or other software component) on another computer over a network. Web services communicate using such technologies as XML, JSON and HTTP. In this chapter, we use two Java APIs that facilitate web services. The first, **JAX-WS**, is based on the **Simple Object Access Protocol (SOAP)**—an XML-based protocol that allows web services and clients to communicate, even if the client and the web service are written in different languages. The second, **JAX-RS**, uses **Representational State Transfer (REST)**—a network architecture that uses the web's traditional request/response mechanisms such as GET and POST requests. For more information on SOAP-based and REST-based web services, visit our Web Services Resource Centers:

www.deitel.com/WebServices/
www.deitel.com/RESTWebServices/

These Resource Centers include information about designing and implementing web services in many languages and about web services offered by companies such as Google, Amazon and eBay. You'll also find many additional tools for publishing and consuming web services. For more information about REST-based Java web services, check out the Jersey project:

jersey.java.net/

The XML used in this chapter is created and manipulated for you by the APIs, so you need not know the details of XML to use it here. To learn more about XML, read the following tutorials:

www.deitel.com/articles/xml_tutorials/20060401/XMLBasics/
www.deitel.com/articles/xml_tutorials/20060401/XMLStructuringData/

and visit our XML Resource Center:

www.deitel.com/XML/

Business-to-Business Transactions

Rather than relying on proprietary applications, businesses can conduct transactions via standardized, widely available web services. This has important implications for **business-to-business (B2B) transactions**. Web services are platform and language independent, enabling companies to collaborate without worrying about the compatibility of their hardware, software and communications technologies. Companies such as Amazon, Google, eBay, PayPal and many others make their server-side applications available to partners via web services.

By purchasing some web services and using other free ones that are relevant to their businesses, companies can spend less time developing applications and can create new ones that are more innovative. E-businesses for example, can provide their customers with enhanced shopping experiences. Consider an online music store. The store's website links to information about various artists, enabling users to purchase their music, to learn about the artists, to find more titles by those artists, to find other artists' music they may enjoy, and more. The store's website may also link to the site of a company that sells concert tickets and provides a web service that displays upcoming concert dates for various artists, allowing users to buy tickets. By consuming the concert-ticket web service on its site, the online music store can provide an additional service to its customers, increase its site traffic and perhaps earn a commission on concert-ticket sales. The company that sells concert tickets also benefits from the business relationship by selling more tickets and possibly by receiving revenue from the online music store for the use of the web service.

Any Java programmer with a knowledge of web services can write applications that "consume" web services. The resulting applications would invoke web services running on servers that could be thousands of miles away.

NetBeans

NetBeans is one of many tools that enable you to *publish* and/or *consume* web services. We demonstrate how to use NetBeans to implement web services using the JAX-WS and JAX-RS APIs and how to invoke them from client applications. For each example, we provide the web service's code, then present a client application that uses the web service. Our first examples build simple web services and client applications in NetBeans. Then we demonstrate web services that use more sophisticated features, such as manipulating databases

32.4 Chapter 32 REST Web Services

with JDBC and manipulating class objects. For information on downloading and installing the NetBeans and the GlassFish server, see Section 30.1.

32.2 Web Service Basics

The machine on which a web service resides is referred to as a **web service host**. The client application sends a request over a network to the web service host, which processes the request and returns a response over the network to the application. This kind of distributed computing benefits systems in various ways. For example, an application without direct access to data on another system might be able to retrieve the data via a web service. Similarly, an application lacking the processing power to perform specific computations could use a web service to take advantage of another system's superior resources.

In Java, a web service is implemented as a class that resides on a server—it's not part of the client application. Making a web service available to receive client requests is known as **publishing a web service**; using a web service from a client application is known as **consuming a web service**.

32.3 Simple Object Access Protocol (SOAP)

The Simple Object Access Protocol (SOAP) is a platform-independent protocol that uses XML to interact with web services, typically over HTTP. You can view the SOAP specification at www.w3.org/TR/soap/. Each request and response is packaged in a **SOAP message**—XML markup containing the information that a web service requires to process the message. SOAP messages are written in XML so that they're computer readable, human readable and platform independent. Most **firewalls**—security barriers that restrict communication among networks—allow HTTP traffic to pass through, so that clients can browse the web by sending requests to and receiving responses from web servers. Thus, SOAP-based services can send and receive SOAP messages over HTTP connections with few limitations.

SOAP supports an extensive set of types, including the primitive types (e.g., `int`), as well as `DateTime`, `XmlNode` and others. SOAP can also transmit arrays of these types. When a program invokes a method of a SOAP web service, the request and all relevant information are packaged in a SOAP message enclosed in a **SOAP envelope** and sent to the server on which the web service resides. When the web service receives this SOAP message, it parses the XML representing the message, then processes the message's contents. The message specifies the *method* that the client wishes to execute and the *arguments* the client passed to that method. Next, the web service calls the method with the specified arguments (if any) and sends the response back to the client in another SOAP message. The client parses the response to retrieve the method's result. In Section 32.6, you'll build and consume a basic SOAP web service.

32.4 Representational State Transfer (REST)

Representational State Transfer (REST) refers to an architectural style for implementing web services. Such web services are often called **RESTful web services**. Though REST itself is not a standard, RESTful web services are implemented using web standards. Each method in a RESTful web service is identified by a unique URL. Thus, when the server receives a request,

32.5 JavaScript Object Notation (JSON)

32_5

it immediately knows what operation to perform. Such web services can be used in a program or directly from a web browser. The results of a particular operation may be cached locally by the browser when the service is invoked with a GET request. This can make subsequent requests for the same operation faster by loading the result directly from the browser's cache. Amazon's web services (aws.amazon.com) are RESTful, as are many others.

RESTful web services are alternatives to those implemented with SOAP. Unlike SOAP-based web services, the request and response of REST services are not wrapped in envelopes. REST is also not limited to returning data in XML format. It can use a variety of formats, such as XML, JSON, HTML, plain text and media files. In Sections 32.7–32.8, you'll build and consume basic RESTful web services.

32.5 JavaScript Object Notation (JSON)

JavaScript Object Notation (JSON) is an alternative to XML for representing data. JSON is a text-based data-interchange format used to represent objects in JavaScript as collections of name/value pairs represented as **Strings**. It's commonly used in Ajax applications. JSON is a simple format that makes objects easy to read, create and parse and, because it's much less verbose than XML, allows programs to transmit data efficiently across the Internet. Each JSON object is represented as a list of property names and values contained in curly braces, in the following format:

```
{ propertyName1 : value1, propertyName2 : value2 }
```

Arrays are represented in JSON with square brackets in the following format:

```
[value1, value2, value3]
```

Each value in an array can be a string, a number, a JSON object, **true**, **false** or **null**. To appreciate the simplicity of JSON data, examine this representation of an array of address-book entries:

```
[{first: 'Cheryl', last: 'Black'},
 {first: 'James', last: 'Blue'},
 {first: 'Mike', last: 'Brown'},
 {first: 'Meg', last: 'Gold'}]
```

Many programming languages now support the JSON data format. An extensive list of JSON libraries sorted by language can be found at www.json.org.

32.6 Publishing and Consuming SOAP-Based Web Services

This section presents our first example of publishing (enabling for client access) and consuming (using) a web service. We begin with a SOAP-based web service.

32.6.1 Creating a Web Application Project and Adding a Web Service Class in NetBeans

When you create a web service in NetBeans, you focus on its logic and let the IDE and server handle its infrastructure. First you create a **Web Application project**. NetBeans uses this project type for web services that are invoked by other applications.

32_6 Chapter 32 REST Web Services

Creating a Web Application Project in NetBeans

To create a web application, perform the following steps:

1. Select **File > New Project...** to open the **New Project** dialog.
2. Select **Java Web** from the dialog's **Categories** list, then select **Web Application** from the **Projects** list. Click **Next >**.
3. Specify **WelcomeSOAP** in the **Project Name** field and specify where you'd like to store the project in the **Project Location** field. You can click the **Browse** button to select the location. Click **Next >**.
4. Select **GlassFish Server 4.1** from the **Server** drop-down list and **Java EE 7 Web** from the **Java EE Version** drop-down list.
5. Click **Finish** to create the project.

This creates a web application that will run in a web browser, similar to the projects used in Chapters 30 and 31.

Adding a Web Service Class to a Web Application Project

Perform the following steps to add a web service class to the project:

1. In the **Projects** tab in NetBeans, right click the **WelcomeSOAP** project's node and select **New > Web Service...** to open the **New Web Service** dialog.
2. Specify **WelcomeSOAP** in the **Web Service Name** field.
3. Specify **com.deitel.welcomesoap** in the **Package** field.
4. Click **Finish** to create the web service class.

The IDE generates a sample web service class with the name from *Step 2* in the package from *Step 3*. You can find this class in your project's **Web Services** node. In this class, you'll define the methods that your web service makes available to client applications. When you eventually build your application, the IDE will generate other supporting files for your web service.

32.6.2 Defining the WelcomeSOAP Web Service in NetBeans

Figure 32.1 contains the completed **WelcomeSOAPService** code (reformatted to match the coding conventions we use in this book). First we discuss this code, then show how to use the NetBeans web service design view to add the **welcome** method to the class.

```

1 // Fig. 32.1: WelcomeSOAP.java
2 // Web service that returns a welcome message via SOAP.
3 package com.deitel.welcomesoap;
4
5 import javax.jws.WebService; // program uses the annotation @WebService
6 import javax.jws.WebMethod; // program uses the annotation @WebMethod
7 import javax.jws.WebParam; // program uses the annotation @WebParam
8

```

Fig. 32.1 | Web service that returns a welcome message via SOAP. (Part 1 of 2.)

32.6 Publishing and Consuming SOAP-Based Web Services

32-7

```

9  @WebService() // annotates the class as a web service
10 public class WelcomeSOAP
11 {
12     // WebMethod that returns welcome message
13     @WebMethod(operationName = "welcome")
14     public String welcome(@WebParam(name = "name") String name)
15     {
16         return "Welcome to JAX-WS web services with SOAP, " + name + "!";
17     }
18 }
```

Fig. 32.1 | Web service that returns a welcome message via SOAP. (Part 2 of 2.)

Annotation import Declarations

Lines 5–7 import the annotations used in this example. By default, each new web service class created with the JAX-WS APIs is a POJO (plain old Java object), so you do *not* need to extend a class or implement an interface to create a web service.

@WebService Annotation

Line 9 contains a **@WebService annotation** (imported at line 5) which indicates that class `WelcomeSOAP` implements a web service. The annotation is followed by parentheses that may contain optional annotation attributes. The optional **name attribute** specifies the name of the service endpoint interface class that will be generated for the client. A **service endpoint interface (SEI)** class (sometimes called a **proxy class**) is used to interact with the web service—a client application consumes the web service by invoking methods on the service endpoint interface object. The optional **serviceName attribute** specifies the service name, which is also the name of the class that the client uses to obtain a service endpoint interface object. If the **serviceName** attribute is not specified, the web service's name is assumed to be the Java class name followed by the word **Service**. NetBeans places the **@WebService** annotation at the beginning of each new web service class you create. You can then add the **name** and **serviceName** properties in the parentheses following the annotation.

When you deploy a web application containing a class that uses the **@WebService** annotation, the server (GlassFish in our case) recognizes that the class implements a web service and creates all the **server-side artifacts** that support the web service—that is, the framework that allows the web service to wait for client requests and respond to those requests once it's deployed on an application server. Some popular open-source application servers that support Java web services include GlassFish (glassfish.dev.java.net), Apache Tomcat (tomcat.apache.org) and JBoss Application Server (www.jboss.com/products/platforms/application).

WelcomeSOAP Service's welcome Method

The `WelcomeSOAP` service has only one method, `welcome` (lines 13–17), which takes the user's name as a `String` and returns a `String` containing a welcome message. This method is tagged with the **@WebMethod annotation** to indicate that it can be called remotely. Any methods that are not tagged with **@WebMethod** are *not* accessible to clients that consume the web service. Such methods are typically utility methods within the web service class. The **@WebMethod** annotation uses the **operationName** attribute to specify the method name

32_8 Chapter 32 REST Web Services

that is exposed to the web service's client. If the `operationName` is not specified, it's set to the actual Java method's name.

Common Programming Error 32.1

Failing to expose a method as a web method by declaring it with the `@WebMethod` annotation prevents clients of the web service from accessing the method. There's one exception—if none of the class's methods are declared with the `@WebMethod` annotation, then all the public methods of the class will be exposed as web methods.

Common Programming Error 32.2

Methods with the `@WebMethod` annotation cannot be static. An object of the web service class must exist for a client to access the service's web methods.

The `name` parameter to `welcome` is annotated with the `@WebParam` annotation (line 14). The optional `@WebParam` attribute `name` indicates the parameter name that is exposed to the web service's clients. If you don't specify the name, the actual parameter name is used.

Completing the Web Service's Code

[Note: If you enter the code in Fig. 32.1 manually, then you can skip the following steps.] NetBeans provides a web service design view in which you can define the method(s) and parameter(s) for your web services. To define the `WelcomeSOAP` class's `welcome` method, perform the following steps:

- With `WelcomeSOAP.java` open in the editor, click the **Design** button at the top of the editor to show the design view (Fig. 32.2).

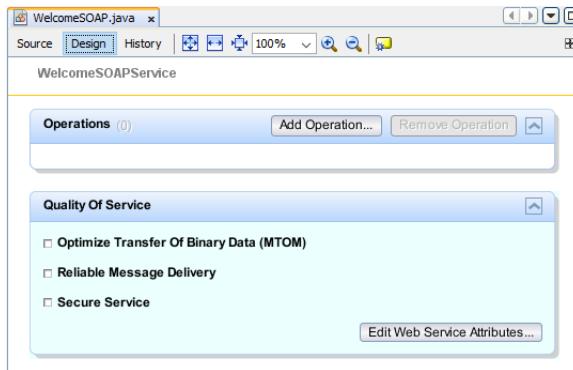

Fig. 32.2 | Web service design view.

- Click the **Add Operation...** button to display the **Add Operation...** dialog (Fig. 32.3).
- Specify the method name `welcome` in the **Name** field. The default **Return Type** (`String`) is correct for this example.

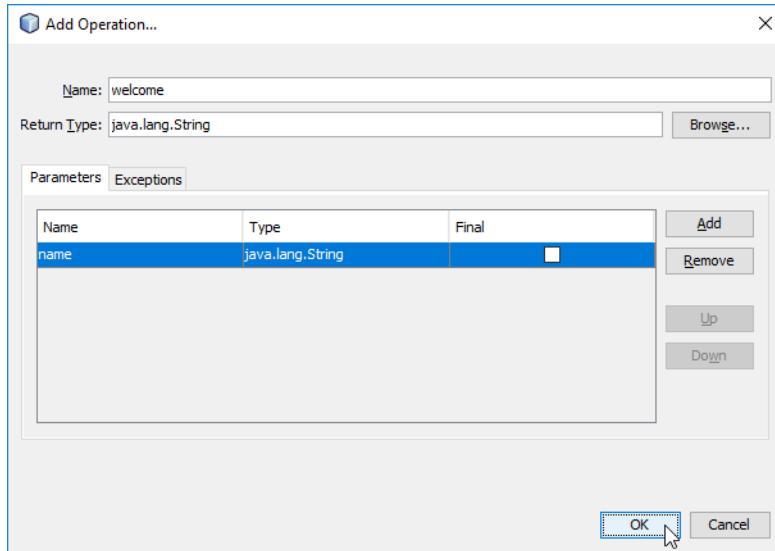

Fig. 32.3 | Adding an operation to a web service.

4. Add the method's name parameter by clicking the Add button to the right of the Parameters tab then entering name in the Name field. The parameter's default Type (String) is correct for this example.
5. Click OK to create the welcome method. The design view should now appear as shown in Fig. 32.3.

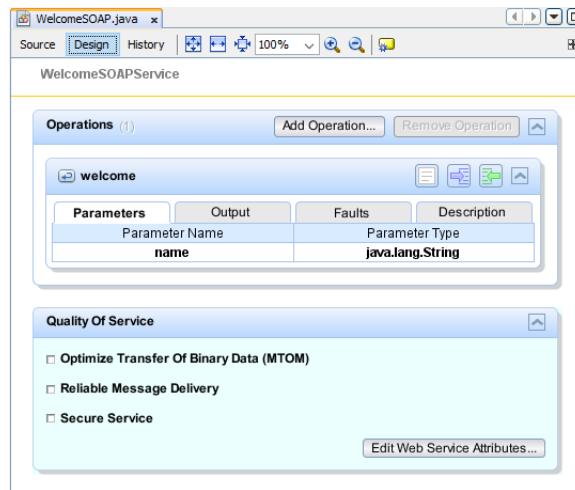

Fig. 32.4 | Web service design view after new operation is added.

32_10 Chapter 32 REST Web Services

- At the top of the design view, click the **Source** button to display the class's source code and add the code line 18 of Fig. 32.1 to the body of method `welcome`.

32.6.3 Publishing the WelcomeSOAP Web Service from NetBeans

Now that you've created the `WelcomeSOAP` web service class, you'll use NetBeans to build and *publish* (that is, deploy) the web service so that clients can consume its services. NetBeans handles all the details of building and deploying a web service for you. This includes creating the framework required to support the web service. Right click the project name `WelcomeSOAP` in the **Projects** tab and select **Deploy** to build and deploy the web application to the GlassFish server. If GlassFish is not already running, NetBeans will start it.

32.6.4 Testing the WelcomeSOAP Web Service with GlassFish Application Server's Tester Web Page

Next, you'll test the `WelcomeSOAP` web service. We previously selected the GlassFish application server to execute this web application. This server can dynamically create a web page that allows you to test a web service's methods from a web browser. To use this capability:

- Expand the project's **Web Services** in the NetBeans **Projects** tab.
- Right click the web service class name (`WelcomeSOAP`) and select **Test Web Service**.

The GlassFish application server builds the **Tester** web page and loads it into your web browser. Figure 32.5 shows the **Tester** web page for the `WelcomeSOAP` web service. The web service's name is automatically the class name followed by **Service**.

Fig. 32.5 | Tester web page created by GlassFish for the `WelcomeSOAP` web service.

Once you've deployed the web service, you can also type the URL

```
http://localhost:8080/WelcomeSOAP/WelcomeSOAPService?Tester
```

in your web browser to view the **Tester** web page. `WelcomeSOAPService` is the name that clients use to access the web service—this is simply the class name followed by **Service**.

To test `WelcomeSOAP`'s `welcome` web method, type your name in the text field to the right of the `welcome` button then click the button to invoke the method. Figure 32.6 shows the results of invoking `WelcomeSOAP`'s `welcome` method with the value `Paul`.

32.6 Publishing and Consuming SOAP-Based Web Services

Fig. 32.6 | Results of testing WelcomeSOAP's welcome method.

Application Server Note

You can access the web service only when the application server is running. If NetBeans launches GlassFish for you, it will automatically shut it down when you close NetBeans. To keep it running, you can launch it independently of NetBeans before you deploy or run web applications. The GlassFish Quick Start Guide at

<https://glassfish.java.net/docs/4.0/quick-start-guide.pdf>

shows how to manually start and stop the server.

Testing the WelcomeSOAP Web Service from Another Computer

If your computer is connected to a network and allows HTTP requests, then you can test the web service from another computer on the network by typing the following URL (where *host* is the hostname or IP address of the computer on which the web service is deployed) into a browser on another computer:

<http://host:8080/WelcomeSOAP/WelcomeSOAPService?Tester>

32.6.5 Describing a Web Service with the Web Service Description Language (WSDL)

To consume a web service, a client must determine its functionality and how to use it. For this purpose, web services normally contain a **service description**. This is an XML document that conforms to the **Web Service Description Language (WSDL)**—an XML vocabulary that defines the methods a web service makes available and how clients interact with them. The WSDL document also specifies lower-level information that clients might need, such as the required formats for requests and responses.

WSDL documents help applications determine how to interact with the web services described in the documents. You do not need to understand WSDL to take advantage of it—the GlassFish application server generates a web service's WSDL dynamically for you, and client tools can parse the WSDL to help create the client-side service endpoint interface class that a client uses to access the web service. Since GlassFish (and most other

32_12 Chapter 32 REST Web Services

servers) generate the WSDL dynamically, clients always receive a deployed web service's most up-to-date description. To access the `WelcomeSOAP` web service, the client code will need the following WSDL URL:

```
http://localhost:8080/WelcomeSOAP/WelcomeSOAPService?WSDL
```

Accessing the `WelcomeSOAP` Web Service's WSDL from Another Computer

Eventually, you'll want clients on other computers to use your web service. Such clients need the web service's WSDL, which they would access with the following URL:

```
http://host:8080/WelcomeSOAP/WelcomeSOAPService?WSDL
```

where `host` is the hostname or IP address of the server that hosts the web service. As we discussed in Section 32.6.4, this works only if your computer allows HTTP connections from other computers—as is the case for publicly accessible web and application servers.

32.6.6 Creating a Client to Consume the `WelcomeSOAP` Web Service

Now you'll consume the web service from a client application. A web service client can be any type of application or even another web service. You enable a client application to consume a web service by **adding a web service reference** to the application.

Service Endpoint Interface (SEI)

An application that consumes a web service consists of an object of a service endpoint interface (SEI) class (sometimes called a *proxy class*) that's used to interact with the web service and a client application that consumes the web service by invoking methods on the service endpoint interface object. The client code invokes methods on the service endpoint interface object, which handles the details of passing method arguments to and receiving return values from the web service on the client's behalf. This communication can occur over a local network, over the Internet or even with a web service on the same computer. The web service performs the corresponding task and returns the results to the service endpoint interface object, which then returns the results to the client code. Figure 32.7 depicts the interactions among the client code, the SEI object and the web service. As you'll soon see, NetBeans creates these service endpoint interface classes for you.

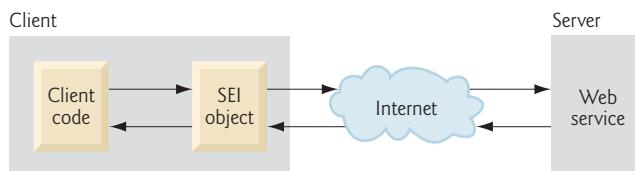

Fig. 32.7 | Interaction between a web service client and a web service.

Requests to and responses from web services created with JAX-WS (one of many different web service frameworks) are typically transmitted via SOAP. Any client capable of generating and processing SOAP messages can interact with a web service, regardless of the language in which the web service is written.

We now use NetBeans to create a client Java desktop GUI application. Then you'll add a web service reference to the project so the client can access the web service. When you add the reference, the IDE creates and compiles the **client-side artifacts**—the framework of Java code that supports the client-side service endpoint interface class. The client then calls methods on an object of the service endpoint interface class, which uses the rest of the artifacts to interact with the web service.

Creating a Desktop Application Project in NetBeans

Before performing the steps in this section, ensure that the `WelcomeSOAP` web service has been deployed and that the GlassFish application server is running (see Section 32.6.3). Perform the following steps to create a client Java desktop application in NetBeans:

1. Select **File > New Project...** to open the **New Project** dialog.
2. Select **Java** from the **Categories** list and **Java Application** from the **Projects** list, then click **Next >**.
3. Specify the name `WelcomeSOAPClient` in the **Project Name** field and uncheck the **Create Main Class** checkbox. Later, you'll add a subclass of `JFrame` that contains a `main` method.
4. Click **Finish** to create the project.

Step 2: Adding a Web Service Reference to an Application

Next, you'll add a web service reference to your application so that it can interact with the `WelcomeSOAP` web service. To add a web service reference, perform the following steps.

1. Right click the project name (`WelcomeSOAPClient`) in the NetBeans **Projects** tab and select **New > Web Service Client...** from the pop-up menu to display the **New Web Service Client** dialog.
2. In the **WSDL URL** field, specify the URL `http://localhost:8080/WelcomeSOAP/WelcomeSOAPService?WSDL` (Fig. 32.8). This URL tells the IDE where to find the web service's WSDL description. [Note: If the GlassFish application server is located on a different computer, replace `localhost` with the hostname or IP address of that computer.] The IDE uses this WSDL description to generate the client-side artifacts that compose and support the service endpoint interface.
3. For the other options, leave the default settings, then click **Finish** to create the web service reference and dismiss the **New Web Service Client** dialog.

In the NetBeans **Projects** tab, the `WelcomeSOAPClient` project now contains a **Web Service References** folder with the `WelcomeSOAP` web service's service endpoint interface (Fig. 32.9). The service endpoint interface's name is listed as `WelcomeSOAPService`.

When you specify the web service you want to consume, NetBeans accesses and copies its WSDL information to a file in your project (named `WelcomeSOAPService.wsdl` in this example). You can view this file by double clicking the `WelcomeSOAPService` node in the project's **Web Service References** folder. If the web service changes, the client-side artifacts and the client's copy of the WSDL file can be regenerated by right clicking the `WelcomeSOAPService` node shown in Fig. 32.9 and selecting **Refresh....** Figure 32.9 also shows the IDE-generated client-side artifacts, which appear in the **Generated Sources (jax-ws)** folder.

32_14 Chapter 32 REST Web Services

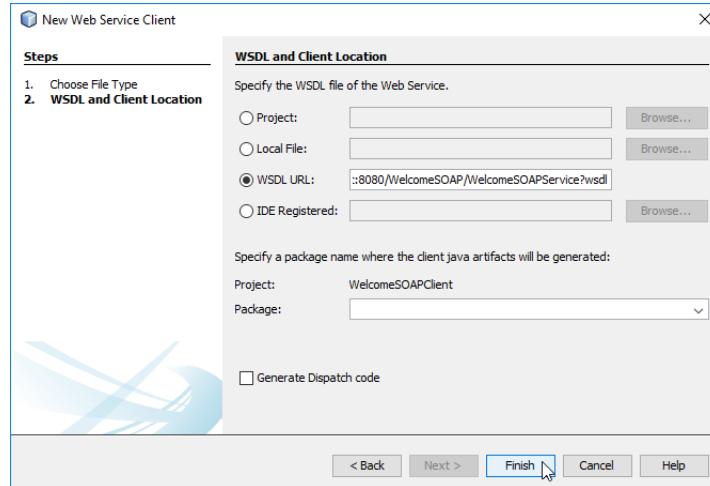

Fig. 32.8 | New Web Service Client dialog.

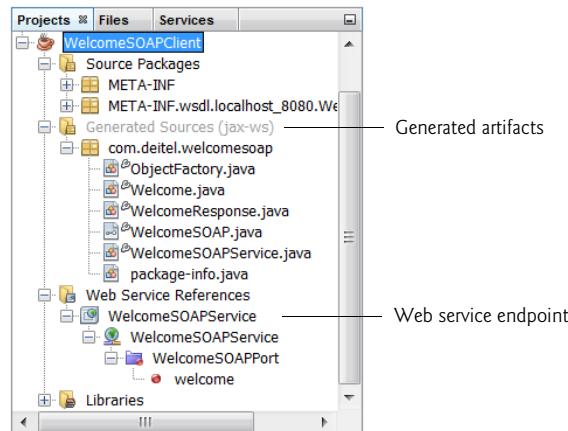

Fig. 32.9 | NetBeans Project tab after adding a web service reference to the project.

32.6.7 Consuming the WelcomeSOAP Web Service

For this example, we use a GUI application to interact with the WelcomeSOAP web service. To build the client application's GUI, add a subclass of `JFrame` to the project by performing the following steps:

1. Right click the project name (`WelcomeSOAPClient`) in the NetBeans Project tab and select `New > JFrame Form...` to display the `New JFrame Form` dialog.
2. Specify `WelcomeSOAPClientJFrame` in the `Class Name` field.
3. Specify `com.deitel.welcomesoapclient` in the `Package` field.
4. Click `Finish` to close the `New JFrame Form` dialog.

32.6 Publishing and Consuming SOAP-Based Web Services

32_15

Next, use the NetBeans GUI design tools to build the GUI shown in the sample screen captures at the end of Fig. 32.10. The GUI consists of a **Label**, a **Text Field** and a **Button**.

The application in Fig. 32.10 uses the `WelcomeSOAP` web service to display a welcome message to the user. To save space, we do not show the NetBeans autogenerated `initComponents` method, which contains the code that creates the GUI components, positions them and registers their event handlers. To view the complete source code, open the `WelcomeSOAPClientJFrame.java` file in this example's folder under `src\java\com\deitel\welcomesoapclient`. NetBeans places the GUI component instance-variable declarations at the end of the class (lines 114–116). Java allows instance variables to be declared anywhere in a class's body as long as they're placed outside the class's methods. We continue to declare our own instance variables at the top of the class.

```

1 // Fig. 32.10: WelcomeSOAPClientJFrame.java
2 // Client desktop application for the WelcomeSOAP web service.
3 package com.deitel.welcomesoapclient;
4
5 import com.deitel.welcomesoap>WelcomeSOAP;
6 import com.deitel.welcomesoap>WelcomeSOAPService;
7 import javax.swing.JOptionPane;
8
9 public class WelcomeSOAPClientJFrame extends javax.swing.JFrame
10 {
11     // references the service endpoint interface object (i.e., the proxy)
12     private WelcomeSOAP welcomeSOAPProxy;
13
14     // no-argument constructor
15     public WelcomeSOAPClientJFrame()
16     {
17         initComponents();
18
19         try
20         {
21             // create the objects for accessing the WelcomeSOAP web service
22             WelcomeSOAPService service = new WelcomeSOAPService();
23             welcomeSOAPProxy = service.getWelcomeSOAPPort();
24         }
25         catch (Exception exception)
26         {
27             exception.printStackTrace();
28             System.exit(1);
29         }
30     }
31
32     // The initComponents method is autogenerated by NetBeans and is called
33     // from the constructor to initialize the GUI. This method is not shown
34     // here to save space. Open WelcomeSOAPClientJFrame.java in this
35     // example's folder to view the complete generated code.
36

32_16 Chapter 32 REST Web Services

```

87     // call the web service with the supplied name and display the message
88     private void submitJButtonActionPerformed(
89         java.awt.event.ActionEvent evt)
90     {
91         String name = nameJTextField.getText(); // get name from JTextField
92
93         // retrieve the welcome string from the web service
94         String message = welcomeSOAPProxy.welcome(name);
95         JOptionPane.showMessageDialog(this, message,
96             "Welcome", JOptionPane.INFORMATION_MESSAGE);
97     }
98
99     // main method begins execution
100    public static void main(String args[])
101    {
102        java.awt.EventQueue.invokeLater(
103            new Runnable()
104            {
105                public void run()
106                {
107                    new WelcomeSOAPClientJFrame().setVisible(true);
108                }
109            }
110        );
111    }
112
113    // Variables declaration - do not modify
114    private javax.swing.JLabel nameLabel;
115    private javax.swing.JTextField nameJTextField;
116    private javax.swing.JButton submitJButton;
117    // End of variables declaration
118 }

```

Fig. 32.10 | Client desktop application for the `WelcomeSOAP` web service. (Part 2 of 2.)

Lines 5–6 import the classes `WelcomeSOAP` and `WelcomeSOAPService` that enable the client application to interact with the web service. Notice that we do not have `import` declarations for most of the GUI components used in this example. When you create a GUI in NetBeans, it uses fully qualified class names (such as `javax.swing.JFrame` in line 9), so `import` declarations are unnecessary.

Line 12 declares a variable of type `WelcomeSOAP` that will refer to the service endpoint interface object. Line 22 in the constructor creates an object of type `WelcomeSOAPService`. Line 23 uses this object's `getWelcomeSOAPPort` method to obtain the `WelcomeSOAP` service endpoint interface object that the application uses to invoke the web service's methods.

The `Submit` button handler (lines 88–97) first retrieves the name the user entered from `nameJTextField`. It then calls the `welcome` method on the service endpoint interface

32.7 Publishing and Consuming REST-Based XML Web Services

32-17

object (line 94) to retrieve the welcome message from the web service. This object communicates with the web service on the client's behalf. Once the message has been retrieved, lines 95–96 display it in a message box by calling `JOptionPane`'s `showMessageDialog` method.

32.7 Publishing and Consuming REST-Based XML Web Services

The previous section used a service endpoint interface (proxy) object to pass data to and from a Java web service using the SOAP protocol. Now, we access a Java web service using the REST architecture. We recreate the `WelcomeSOAP` example to return data in plain XML format. You can create a **Web Application** project as you did in Section 32.6 to begin. Name the project `WelcomeRESTXML`.

32.7.1 Creating a REST-Based XML Web Service

NetBeans provides various templates for creating RESTful web services, including ones that can interact with databases on the client's behalf. In this chapter, we focus on simple RESTful web services. To create a RESTful web service:

1. Right-click the `WelcomeRESTXML` node in the **Projects** tab, and select **New > Other...** to display the **New File** dialog.
2. Select **Web Services** under **Categories**, then select **RESTful Web Services** from **Patterns** and click **Next >**.
3. Under **Select Pattern**, ensure **Simple Root Resource** is selected, and click **Next >**.
4. Set the **Resource Package** to `com.deitel.welcomerestxml`, the **Path** to `welcome` and the **Class Name** to `WelcomeRESTXMLResource`. Leave the **MIME Type** and **Representation Class** set to `application/xml` and `java.lang.String`, respectively. The correct configuration is shown in Fig. 32.11.
5. Click **Finish** to create the web service.

NetBeans generates the class and sets up the proper annotations. The class is placed in the project's **RESTful Web Services** folder. The code for the completed service is shown in Fig. 32.12. You'll notice that the completed code does not include some of the code generated by NetBeans. We removed the pieces that were unnecessary for this simple web service. The autogenerated `putXml` method is not necessary, because this example does not modify state on the server. The `UriInfo` instance variable is not needed, because we do not use HTTP query parameters. We also removed the autogenerated constructor, because we have no code to place in it.

Lines 6–9 contain the imports for the JAX-RS annotations that help define the RESTful web service. The `@Path annotation` on the `WelcomeRESTXMLResource` class (line 12) indicates the URI for accessing the web service. This URI is appended to the web application project's URL to invoke the service. Methods of the class can also use the `@Path annotation` (line 17). Parts of the path specified in curly braces indicate parameters—they're placeholders for values that are passed to the web service as part of the path.

32_18 Chapter 32 REST Web Services

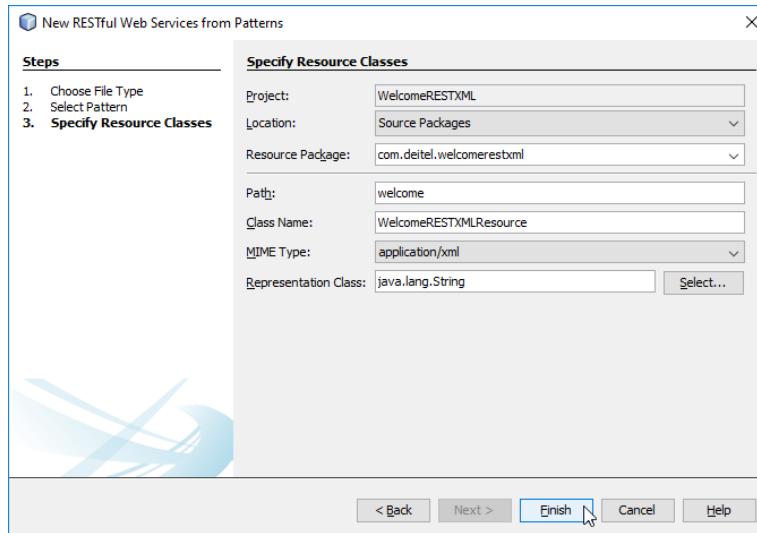

Fig. 32.11 | Creating the WelcomeRESTXML RESTful web service.

```

1 // Fig. 32.12: WelcomeRESTXMLResource.java
2 // REST web service that returns a welcome message as XML.
3 package com.deitel.welcomerestxml;
4
5 import java.io.StringWriter;
6 import javax.ws.rs.GET; // annotation to indicate method uses HTTP GET
7 import javax.ws.rs.Path; // annotation to specify path of resource
8 import javax.ws.rsPathParam; // annotation to get parameters from URI
9 import javax.ws.rs.Produces; // annotation to specify type of data
10 import javax.xml.bind.JAXB; // utility class for common JAXB operations
11
12 @Path("welcome") // URI used to access the resource
13 public class WelcomeRESTXMLResource
14 {
15     // retrieve welcome message
16     @GET // handles HTTP GET requests
17     @Path("{name}") // URI component containing parameter
18     @Produces("application/xml") // response formatted as XML
19     public String getXml(@PathParam("name") String name)
20     {
21         String message = "Welcome to JAX-RS web services with REST and " +
22             "XML, " + name + "!"; // our welcome message
23         StringWriter writer = new StringWriter();
24         JAXB.marshal(message, writer); // marshal String as XML
25         return writer.toString(); // return XML as String
26     }
27 }
```

Fig. 32.12 | REST web service that returns a welcome message as XML.

32.7 Publishing and Consuming REST-Based XML Web Services

32_19

The base path for the service is the project's `webresources` directory. For example, to get a welcome message for someone named John, the complete URL is

```
http://localhost:8080/WelcomeRESTXML/webresources/welcome/John
```

Arguments in a URL can be used as arguments to a web service method. To do so, you bind the parameters specified in the `@Path` specification to parameters of the web service method with the `@PathParam annotation`, as shown in line 19. When the request is received, the server passes the argument(s) in the URL to the appropriate parameter(s) in the web service method.

The `@GET annotation` denotes that this method is accessed via an HTTP GET request. The `putXml` method the IDE created for us had an `@PUT` annotation, which indicates that the method is accessed using the HTTP PUT method. Similar annotations exist for HTTP POST, DELETE and HEAD requests.

The `@Produces annotation` denotes the content type returned to the client. It's possible to have multiple methods with the same HTTP method and path but different `@Produces` annotations, and JAX-RS will call the method matching the content type requested by the client. Standard Java method overloading rules apply, so such methods must have different names. The `@Consumes annotation` for the autogenerated `putXml` method (which we deleted) restricts the content type that the web service will accept from a PUT operation.

Line 10 imports the `JAXB class` from package `javax.xml.bind`. **JAXB (Java Architecture for XML Binding)** is a set of classes for converting POJOs to and from XML. There are many related classes in the same package that implement the serializations we perform, but the `JAXB class` contains easy-to-use wrappers for common operations. After creating the welcome message (lines 21–22), we create a `StringWriter` (line 23) to which JAXB will output the XML. Line 24 calls the `JAXB class's static method marshal` to convert the `String` containing our message to XML format. Line 25 calls `StringWriter's toString` method to retrieve the XML text to return to the client.

Testing the RESTful Web Service

Section 32.6.4 demonstrated testing a SOAP service using GlassFish's `Tester` page. GlassFish does not provide a testing facility for RESTful services, but you can enter the web service's URL directly in your browser to test the web service. To do so:

1. First, deploy the web service's project. Right click the `WelcomeRESTXML` project in the NetBeans `Projects` tab and select `Deploy`. This will compile and deploy the web service, if you have not yet done so.
2. Open a web browser and enter the following URL in the browser's address bar:
`http://localhost:8080/WelcomeRESTXML/webresources/welcome/Paul`—you can replace `Paul` with your own name.

Once GlassFish deploys a REST web service, a client can access it on the server (in this case, `localhost` at port 8080) at the location

```
/ProjectName/webresources/methodName
```

If the method requires parameters, as in this example, each parameter follows the method name in the form

```
/argument
```

32_20 Chapter 32 REST Web Services

and the arguments are passed to the method's parameters in the same order as they're declared in the method's parameter list. So the URL

```
http://localhost:8080/WelcomeRESTXML/webresources/welcome/Paul
```

invokes the `WelcomeRESTXML` web service's `welcome` method and passes `Paul` to the method's `name` parameter. The web service then returns an XML response that's displayed directly in the web browser (Fig. 32.13).

Fig. 32.13 | Test page for the `WelcomeRESTXML` web service.

WADL

WADL (Web Application Description Language) has similar design goals to WSDL, but describes RESTful services instead of SOAP services. You can access this app's WADL at

```
http://localhost:8080/WelcomeRESTJSON/webresources/application.wadl
```

Client-code-generation tools can use this description to help implement a client that interacts with this web service.

32.7.2 Consuming a REST-Based XML Web Service

As we did with SOAP, we create a Java application that retrieves the welcome message from the web service and displays it to the user. First, create a Java application with the name `WelcomeRESTXMLClient`. RESTful web services do *not* require web service references, so you can begin building the GUI immediately by creating a `JFrame` form called `WelcomeRESTXMLClientJFrame` and placing it in the `com.deitel.welcomerestxmlclient` package. The GUI is identical to the one in Fig. 32.10, including the names of the GUI elements. To create the GUI quickly, you can simply copy and paste the GUI from the `Design` view of the `WelcomeSOAPClientJFrame` class and paste it into the `Design` view of the `WelcomeRESTXMLClientJFrame` class. Figure 32.14 contains the completed code.

```
1 // Fig. 32.14: WelcomeRESTXMLClientJFrame.java
2 // Client that consumes the WelcomeRESTXML service.
3 package com.deitel.welcomerestxmlclient;
4
5 import javax.swing.JOptionPane;
```

Fig. 32.14 | Client that consumes the `WelcomeRESTXML` service. (Part 1 of 3.)

32.7 Publishing and Consuming REST-Based XML Web Services

32_21

```

6  import javax.xml.bind.JAXB; // utility class for common JAXB operations
7
8  public class WelcomeRESTXMLClientJFrame extends javax.swing.JFrame
9  {
10     // no-argument constructor
11     public WelcomeRESTXMLClientJFrame()
12     {
13         initComponents();
14     }
15
16     // The initComponents method is autogenerated by NetBeans and is called
17     // from the constructor to initialize the GUI. This method is not shown
18     // here to save space. Open WelcomeRESTXMLClientJFrame.java in this
19     // example's folder to view the complete generated code.
20
21     // call the web service with the supplied name and display the message
22     private void submitJButtonActionPerformed(
23         java.awt.event.ActionEvent evt)
24     {
25         String name = nameJTextField.getText(); // get name from JTextField
26
27         // the URL for the REST service
28         String url = "http://localhost:8080/WelcomeRESTXML/" +
29             "webresources/welcome/" + name;
30
31         // read from URL and convert from XML to Java String
32         String message = JAXB.unmarshal(url, String.class);
33
34         // display the message to the user
35         JOptionPane.showMessageDialog(this, message,
36             "Welcome", JOptionPane.INFORMATION_MESSAGE);
37     }
38
39     // main method begins execution
40     public static void main(String args[])
41     {
42         java.awt.EventQueue.invokeLater(
43             new Runnable()
44             {
45                 public void run()
46                 {
47                     new WelcomeRESTXMLClientJFrame().setVisible(true);
48                 }
49             }
50         );
51     }
52
53     // Variables declaration - do not modify
54     private javax.swing.JLabel nameLabel;
55     private javax.swing.JTextField nameJTextField;
56     private javax.swing.JButton submitJButton;
57
58     // End of variables declaration
59 }

```

Fig. 32.14 | Client that consumes the WelcomeRESTXML service. (Part 2 of 3.)

32.22 Chapter 32 REST Web Services

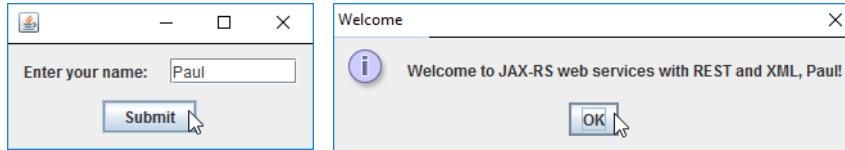

Fig. 32.14 | Client that consumes the WelcomeRESTXML service. (Part 3 of 3.)

You can access a RESTful web service with classes from Java API. As in the RESTful XML web service, we use the JAXB library. The JAXB class (imported on line 6) has a static `unmarshal` method that takes as arguments a filename or URL as a `String`, and a `Class<T>` object indicating the Java class to which the XML will be converted (line 83). In this example, the XML contains a `String` object, so we use the Java compiler shortcut `String.class` to create the `Class<String>` object we need as the second argument. The `String` returned from the call to the `unmarshal` method is then displayed to the user via `JOptionPane`'s `showMessageDialog` method (lines 86–87), as it was with the SOAP service. The URL used in this example to extract data from the web service matches the URL we used to test the web service directly in a web browser.

32.8 Publishing and Consuming REST-Based JSON Web Services

While XML was designed primarily as a document interchange format, JSON is designed as a *data* exchange format. Data structures in most programming languages do not map directly to XML constructs—for example, the distinction between elements and attributes is not present in programming-language data structures. JSON is a subset of the JavaScript programming language, and its components—objects, arrays, strings, numbers—can be easily mapped to constructs in Java and other programming languages.

The standard Java libraries do not currently provide capabilities for working with JSON, but there are many open-source JSON libraries for Java and other languages; you can find a list of them at json.org. We chose the Gson library from <https://github.com/google/gson>, which provides a simple way to convert POJOs to and from JSON. A JAR file containing the library can be downloaded from

```
http://search.maven.org/remotecontent?filepath=com/google/code/
gson/gson/2.7/gson-2.7.jar
```

32.8.1 Creating a REST-Based JSON Web Service

To begin, create a `WelcomeRESTJSON` web application, then create the web service by following the steps in Section 32.7.1. In *Step 4*, change the **Resource Package** to `com.deitel.welcomerestjson`, the **Class Name** to `WelcomeRESTJSONResource` and the **MIME Type** to `application/json`. Additionally, you must download the Gson library's JAR file, then add it to the project as a library. To add the JAR file to the project, right click your project's **Libraries** folder, select **Add JAR/Folder...** locate the downloaded Gson JAR file and click **Open**. The complete code for the service is shown in Fig. 32.15.

32.8 Publishing and Consuming REST-Based JSON Web Services

32_23

```

1 // Fig. 32.15: WelcomeRESTJSONResource.java
2 // REST web service that returns a welcome message as JSON.
3 package com.deitel.welcomerestjson;
4
5 import com.google.gson.Gson; // converts POJO to JSON and back again
6 import javax.ws.rs.GET; // annotation to indicate method uses HTTP GET
7 import javax.ws.rs.Path; // annotation to specify path of resource
8 import javax.ws.rsPathParam; // annotation to get parameters from URI
9 import javax.ws.rs.Produces; // annotation to specify type of data
10
11 @Path("welcome") // path used to access the resource
12 public class WelcomeRESTJSONResource
13 {
14     // retrieve welcome message
15     @GET // handles HTTP GET requests
16     @Path("{name}") // takes name as a path parameter
17     @Produces("application/json") // response formatted as JSON
18     public String getJson(@PathParam("name") String name)
19     {
20         // add welcome message to field of TextMessage object
21         TextMessage message = new TextMessage(); // create wrapper object
22         message.setMessage(String.format("%s, %s!",
23             "Welcome to JAX-RS web services with REST and JSON", name));
24
25         return new Gson().toJson(message); // return JSON-wrapped message
26     }
27 }
28
29 // private class that contains the message we wish to send
30 class TextMessage
31 {
32     private String message; // message we're sending
33
34     // returns the message
35     public String getMessage()
36     {
37         return message;
38     }
39
40     // sets the message
41     public void setMessage(String value)
42     {
43         message = value;
44     }
45 }
```

Fig. 32.15 | REST web service that returns a welcome message as JSON.

All the annotations and the basic structure of the `WelcomeRESTJSONResource` class are the same as REST XML example. The argument to the `@Produces` attribute (line 17) is "application/json". The `TextMessage` class (lines 30–45) addresses a difference between JSON and XML. JSON does not permit strings or numbers to stand on their

32.24 Chapter 32 REST Web Services

own—they must be encapsulated in a composite data type. So, we created class `TextMessage` to encapsulate the `String` representing the message.

When a client invokes this web service, line 21 creates the `TextMessage` object, then lines 22–23 set its contained message. Next, line 25 creates a `Gson` object (from package `com.google.gson.Gson`) and calls its `toJson` method to convert the `TextMessage` into its JSON `String` representation. We return this `String`, which is then sent back to the client in the web service's response. There are multiple overloads of the `toJson` method, such as one that sends its output to a `Writer` instead of returning a `String`.

RESTful services returning JSON can be tested in the same way as those returning XML. Follow the procedure outlined in Section 32.7.1, but use the URL

```
http://localhost:8080/WelcomeRESTJSON/webresources/welcome/Paul
```

to invoke the web service. In this case, the browser will display the JSON response

```
{"message": "Welcome to JAX-RS web services with REST and JSON, Paul!"}
```

32.8.2 Consuming a REST-Based JSON Web Service

We now create a Java application that retrieves the welcome message from the web service and displays it to the user. First, create a Java application with the name `WelcomeRESTJSONClient`. Then, create a `JFrame` form called `WelcomeRESTXMLClientJFrame` and place it in the `com.deitel.welcomerestjsonclient` package. The GUI is identical to the one in Fig. 32.10. To create the GUI quickly, copy it from the `Design` view of the `WelcomeSOAPClientJFrame` class and paste it into the `Design` view of the `WelcomeRESTJSONClientJFrame` class. Figure 32.16 contains the completed code.

```

1 // Fig. 32.16: WelcomeRESTJSONClientJFrame.java
2 // Client that consumes the WelcomeRESTJSON service.
3 package com.deitel.welcomerestjsonclient;
4
5 import com.google.gson.Gson; // converts POJO to JSON and back again
6 import java.io.InputStreamReader;
7 import java.net.URL;
8 import javax.swing.JOptionPane;
9
10 public class WelcomeRESTJSONClientJFrame extends javax.swing.JFrame
11 {
12     // no-argument constructor
13     public WelcomeRESTJSONClientJFrame()
14     {
15         initComponents();
16     }
17
18     // The initComponents method is autogenerated by NetBeans and is called
19     // from the constructor to initialize the GUI. This method is not shown
20     // here to save space. Open WelcomeRESTJSONClientJFrame.java in this
21     // example's folder to view the complete generated code.
22 }
```

Fig. 32.16 | Client that consumes the `WelcomeRESTJSON` service. (Part 1 of 3.)

32.8 Publishing and Consuming REST-Based JSON Web Services

32_25

```

73     // call the web service with the supplied name and display the message
74     private void submitJButtonActionPerformed(
75         java.awt.event.ActionEvent evt)
76     {
77         String name = nameJTextField.getText(); // get name from JTextField
78
79         // retrieve the welcome string from the web service
80         try
81         {
82             // the URL of the web service
83             String url = "http://localhost:8080/WelcomeRESTJSON/" +
84                 "webresources/welcome/" + name;
85
86             // open URL, using a Reader to convert bytes to chars
87             InputStreamReader reader =
88                 new InputStreamReader(new URL(url).openStream());
89
90             // parse the JSON back into a TextMessage
91             TextMessage message =
92                 new Gson().fromJson(reader, TextMessage.class);
93
94             // display message to the user
95             JOptionPane.showMessageDialog(this, message.getMessage(),
96                 "Welcome", JOptionPane.INFORMATION_MESSAGE);
97         }
98         catch (Exception exception)
99         {
100             exception.printStackTrace(); // show exception details
101         }
102     }
103
104    // main method begin execution
105    public static void main(String args[])
106    {
107        java.awt.EventQueue.invokeLater(
108            new Runnable()
109            {
110                public void run()
111                {
112                    new WelcomeRESTJSONClientJFrame().setVisible(true);
113                }
114            }
115        );
116    }
117
118    // Variables declaration - do not modify
119    private javax.swing.JLabel nameJLabel;
120    private javax.swing.JTextField nameJTextField;
121    private javax.swing.JButton submitJButton;
122    // End of variables declaration
123 }
124

```

Fig. 32.16 | Client that consumes the WelcomeRESTJSON service. (Part 2 of 3.)

32.26 Chapter 32 REST Web Services

```

125 // private class that contains the message we are receiving
126 class TextMessage
127 {
128     private String message; // message we're receiving
129
130     // returns the message
131     public String getMessage()

```

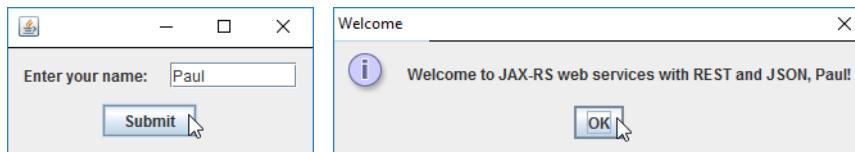

Fig. 32.16 | Client that consumes the WelcomeRESTJSON service. (Part 3 of 3.)

Lines 83–84 create the URL String that is used to invoke the web service. Lines 87–88 create a URL object using this String, then call the URL’s `openStream` method to invoke the web service and obtain an `InputStream` from which the client can read the response. The `InputStream` is wrapped in an `InputStreamReader` so it can be passed as the first argument to the `Gson` class’s `fromJson` method. This method is overloaded. The version we use takes as arguments a `Reader` from which to read a JSON String and a `Class<T>` object indicating the Java class to which the JSON String will be converted (line 92). In this example, the JSON String contains a `TextMessage` object, so we use the Java compiler shortcut `TextMessage.class` to create the `Class<TextMessage>` object we need as the second argument. Lines 95–96 display the message in the `TextMessage` object.

The `TextMessage` classes in the web service and client are unrelated. Technically, the client can be written in any programming language, so the manner in which a response is processed can vary greatly. Since our client is written in Java, we duplicated the `TextMessage` class in the client so we could easily convert the JSON object back to Java.

32.9 Session Tracking in a SOAP Web Service

Section 30.8 described the advantages of using session tracking to maintain client-state information so you can personalize the users’ browsing experiences. Now we’ll incorporate *session tracking* into a web service. Suppose a client application needs to call several methods from the same web service, possibly several times each. In such a case, it can be beneficial for the web service to maintain state information for the client, thus eliminating the need for client information to be passed between the client and the web service multiple

32.9 Session Tracking in a SOAP Web Service

32_27

times. For example, a web service that provides local restaurant reviews could store the client user's street address during the initial request, then use it to return personalized, localized results in subsequent requests. Storing session information also enables a web service to distinguish between clients.

32.9.1 Creating a Blackjack Web Service

Our next example is a web service that assists you in developing a blackjack card game. The `Blackjack` web service (Fig. 32.17) provides web methods to shuffle a deck of cards, deal a card from the deck and evaluate a hand of cards. After presenting the web service, we use it to serve as the dealer for a game of blackjack (Fig. 32.18). The `Blackjack` web service uses an `HttpSession` object to maintain a unique deck of cards for each client application. Several clients can use the service at the same time, but web method calls made by a specific client use only the deck of cards stored in that client's session. Our example uses the following blackjack rules:

Two cards each are dealt to the dealer and the player. The player's cards are dealt face up. Only the first of the dealer's cards is dealt face up. Each card has a value. A card numbered 2 through 10 is worth its face value. Jacks, queens and kings each count as 10. Aces can count as 1 or 11—whichever value is more beneficial to the player (as we'll soon see). If the sum of the player's two initial cards is 21 (i.e., the player was dealt a card valued at 10 and an ace, which counts as 11 in this situation), the player has "blackjack" and immediately wins the game—if the dealer does not also have blackjack (which would result in a "push"—i.e., a tie). Otherwise, the player can begin taking additional cards one at a time. These cards are dealt face up, and the player decides when to stop taking cards. If the player "busts" (i.e., the sum of the player's cards exceeds 21), the game is over and the player loses. When the player is satisfied with the current set of cards, the player "stands" (i.e., stops taking cards), and the dealer's hidden card is revealed. If the dealer's total is 16 or less, the dealer must take another card; otherwise, the dealer must stand. The dealer must continue taking cards until the sum of the dealer's cards is greater than or equal to 17. If the dealer exceeds 21, the player wins. Otherwise, the hand with the higher point total wins. If the dealer and the player have the same point total, the game is a "push," and no one wins. The value of an ace for a dealer depends on the dealer's other card(s) and the casino's house rules. A dealer typically must hit for totals of 16 or less and must stand for totals of 17 or more. However, for a "soft 17"—a hand with a total of 17 with one ace counted as 11—some casinos require the dealer to hit and some require the dealer to stand (we require the dealer to stand). Such a hand is known as a "soft 17" because taking another card cannot bust the hand.

The web service (Fig. 32.17) stores each card as a `String` consisting of a number, 1–13, representing the card's face (ace through king, respectively), followed by a space and a digit, 0–3, representing the card's suit (hearts, diamonds, clubs or spades, respectively). For example, the jack of clubs is represented as "11 2" and the two of hearts as "2 0". To create and deploy this web service, follow the steps that we presented in Sections 32.6.2–32.6.3 for the `WelcomeSOAP` service.

97         return total;
98     }
99 }
```

Fig. 32.17 | Blackjack web service that deals cards and evaluates hands. (Part 2 of 2.)*Session Tracking in Web Services: @HttpSessionScope Annotation*

In JAX-WS 2.2, it's easy to enable session tracking in a web service. You simply precede your web service class with the **@HttpSessionScope annotation**. This annotation is located in package `com.sun.xml.ws.developer.servlet`. To use this package you must add the JAX-WS 2.2 library to your project. To do so, right click the **Libraries** node in your Black-

32_30 Chapter 32 REST Web Services

jack web application project and select **Add Library**.... Then, in the dialog that appears, locate and select **JAX-WS 2.2**, then click **Add Library**. Once a web service is annotated with `@HttpSessionScope`, the server automatically maintains a separate instance of the class for each client session. Thus, the `deck` instance variable (line 16) will be maintained separately for each client.

Client Interactions with the Blackjack Web Service

A client first calls the `Blackjack` web service's `shuffle` web method (lines 30–53) to create a new deck of cards (line 34), populate it (lines 37–39) and shuffle it (lines 41–52). Lines 37–39 generate `Strings` in the form "`face suit`" to represent each possible card in the deck.

Lines 20–27 define the `dealCard` web method. Method `shuffle` *must* be called before method `dealCard` is called the first time for a client—otherwise, `deck` could be `null`. The method gets the top card from the deck (line 24), removes it from the deck (line 25) and returns the card's value as a `String` (line 26). Without using session tracking, the deck of cards would need to be passed back and forth with each method call. Session tracking makes the `dealCard` method easy to call (it requires no arguments) and eliminates the overhead of sending the deck over the network multiple times.

Method `getHandValue` (lines 56–98) determines the total value of the cards in a hand by trying to attain the highest score possible without going over 21. Recall that an ace can be counted as either 1 or 11, and all face cards count as 10. This method does not use the `session` object, because the deck of cards is not used in this method.

As you'll soon see, the client application maintains a hand of cards as a `String` in which each card is separated by a tab character. Line 60 splits the hand of cards (represented by `hand`) into individual cards by calling `String` method `split` and passing to it a `String` containing the delimiter characters (in this case, just a tab). Method `split` uses the delimiter characters to separate tokens in the `String`. Lines 65–85 count the value of each card. Lines 68–69 retrieve the first integer—the face—and use that value in the `switch` statement (lines 71–84). If the card is an ace, the method increments variable `aceCount`. We discuss how this variable is used shortly. If the card is an 11, 12 or 13 (jack, queen or king), the method adds 10 to the total value of the hand (line 79). If the card is anything else, the method increases the total by that value (line 82).

Because an ace can have either of two values, additional logic is required to process aces. Lines 88–95 process the aces after all the other cards. If a hand contains several aces, only one ace can be counted as 11. The condition in line 91 determines whether counting one ace as 11 and the rest as 1 will result in a total that does not exceed 21. If this is possible, line 92 adjusts the total accordingly. Otherwise, line 94 adjusts the total, counting each ace as 1.

Method `getHandValue` maximizes the value of the current cards without exceeding 21. Imagine, for example, that the dealer has a 7 and receives an ace. The new total could be either 8 or 18. However, `getHandValue` always maximizes the value of the cards without going over 21, so the new total is 18.

32.9.2 Consuming the Blackjack Web Service

The blackjack application in Fig. 32.18 keeps track of the player's and dealer's cards, and the web service tracks the cards that have been dealt. The constructor (lines 34–83) sets up the GUI (line 36), changes the window's background color (line 40) and creates the `Blackjack` web service's service endpoint interface object (lines 46–47). In the GUI, each

32.9 Session Tracking in a SOAP Web Service

32_31

player has 11 `JLabels`—the maximum number of cards that can be dealt without automatically exceeding 21 (i.e., four aces, four twos and three threes). These `JLabels` are placed in an `ArrayList` of `JLabels` (lines 59–82), so we can index the `ArrayList` during the game to determine the `JLabel` that will display a particular card image.

Configuring the Client for Session Tracking

When interacting with a JAX-WS web service that performs session tracking, the client application must indicate whether it wants to allow the web service to maintain session information. Lines 50–51 in the constructor perform this task. We first cast the service endpoint interface object to interface type `BindingProvider`. A `BindingProvider` enables the client to manipulate the request information that will be sent to the server. This information is stored in an object that implements interface `RequestContext`. The `BindingProvider` and `RequestContext` are part of the framework that is created by the IDE when you add a web service client to the application. Next, we invoke the `BindingProvider`'s `get RequestContext` method to obtain the `RequestContext` object. Then we call the `RequestContext`'s `put` method to set the property

```
BindingProvider.SESSION_MAINTAIN_PROPERTY
```

to true. This enables the client side of the session-tracking mechanism, so that the web service knows which client is invoking the service's web methods.

Method `gameOver`

Method `gameOver` (lines 195–233) displays all the dealer's cards, shows the appropriate message in `statusJLabel` and displays the final point totals of both the dealer and the player. Method `gameOver` receives as an argument a member of the `GameStatus` enum (defined in lines 25–31). The enum constants represent whether the player tied, lost or won the game; its four members are `PUSH`, `LOSE`, `WIN` and `BLACKJACK`.

32.9 Session Tracking in a SOAP Web Service

32_41

Method dealJButtonActionPerformed

When the player clicks the **Deal JButton**, method `dealJButtonActionPerformed` (lines 543–602) clears all of the `JLabels` that display cards or game status information. Next, the deck is shuffled (line 559), and the player and dealer receive two cards each (lines 562–573). Lines 580–581 then total each hand. If the player and the dealer both obtain scores of 21, the program calls method `gameOver`, passing `GameStatus.PUSH` (line 586). If only the dealer has 21, the program passes `GameStatus.LOSE` to method `gameOver` (line 590). If only the player has 21 after the first two cards are dealt, the program passes `GameStatus.BLACKJACK` to method `gameOver` (line 594).

Method hitJButtonActionPerformed

If `dealJButtonActionPerformed` does not call `gameOver`, the player can take more cards by clicking the **Hit JButton**, which calls `hitJButtonActionPerformed` in lines 605–628. Each time a player clicks **Hit**, the program deals the player one more card (line 609) and displays it in the GUI (line 613). If the player exceeds 21, the game is over and the player loses (line 621). If the player has exactly 21, the player is not allowed to take any more cards (line 625), and method `dealerPlay` is called (line 626).

Method dealerPlay

Method `dealerPlay` (lines 86–139) displays the dealer's cards, then deals cards to the dealer until the dealer's hand has a value of 17 or more (lines 100–108). If the dealer exceeds 21, the player wins (line 116); otherwise, the values of the hands are compared, and `gameOver` is called with the appropriate argument (lines 122–133).

Method standJButtonActionPerformed

Clicking the **Stand JButton** indicates that a player does not want to be dealt another card. Method `standJButtonActionPerformed` (lines 631–638) disables the **Hit** and **Stand** buttons, enables the **Deal** button, then calls method `dealerPlay`.

Method displayCard

Method `displayCard` (lines 142–192) updates the GUI to display a newly dealt card. The method takes as arguments an integer index for the `JLabel` in the `ArrayList` that must have its image set and a `String` representing the card. An empty `String` indicates that we wish to display the card face down. If method `displayCard` receives a `String` that's not empty, the program extracts the face and suit from the `String` and uses this information to display the correct image. The `switch` statement (lines 167–181) converts the number representing the suit to an integer and assigns the appropriate character to variable `suitLetter` (`h` for hearts, `d` for diamonds, `c` for clubs and `s` for spades). The character in `suitLetter` is used to complete the image's filename (lines 184–186). *You must add the folder blackjack_images to your project so that lines 152–154 and 184–186 can access the images properly.* To do so, copy the folder `blackjack_images` from this chapter's examples folder and paste it into the project's `src\com\deitel\java\blackjackclient` folder.

32.42 Chapter 32 REST Web Services

32.10 Consuming a Database-Driven SOAP Web Service

Our prior examples accessed web services from desktop applications created in NetBeans. However, we can just as easily use them in web applications created with NetBeans. In fact, because web-based businesses are becoming increasingly popular, it's common for web applications to consume web services. In this section, we present an airline reservation web service that receives information regarding the type of seat a customer wishes to reserve and makes a reservation if such a seat is available. Later in the section, we present a web application that allows a customer to specify a reservation request, then uses the airline reservation web service to attempt to execute the request.

32.10.1 Creating the Reservation Database

Our web service uses a reservation database containing a single table named Seats to locate a seat matching a client's request. Review the steps presented in Section 31.2.1 for configuring a data source and the addressbook database. Then perform those steps for the reservation database used in this example. This chapter's examples directory contains the Seats.sql SQL script to create the seats table and populate it with sample data. The sample data is shown in Fig. 32.19.

number	location	class	taken
1	Aisle	Economy	0
2	Aisle	Economy	0
3	Aisle	First	0
4	Middle	Economy	0
5	Middle	Economy	0
6	Middle	First	0
7	Window	Economy	0
8	Window	Economy	0
9	Window	First	0
10	Window	First	0

Fig. 32.19 | Data from the seats table.

Creating the Reservation Web Service

You can now create a web service that uses the reservation database (Fig. 32.20). We used the @DataSourceDefinition annotation (lines 17–23) to create a data source named

```
java:global/jdbc/reservation
```

for accessing the database.

```

1 // Fig. 32.20: Reservation.java
2 // Airline reservation web service.
3 package com.deitel.reservation;
4
```

Fig. 32.20 | Airline reservation web service. (Part 1 of 3.)

32.10 Consuming a Database-Driven SOAP Web Service

32_43

```

5  import java.sql.Connection;
6  import java.sql.PreparedStatement;
7  import java.sql.ResultSet;
8  import java.sql.SQLException;
9  import javax.annotation.Resource;
10 import javax.annotation.sql.DataSourceDefinition;
11 import javax.jws.WebMethod;
12 import javax.jws.WebParam;
13 import javax.jws.WebService;
14 import javax.sql.DataSource;
15
16 // define the data source
17 @DataSourceDefinition(
18     name = "java:global/jdbc/reservation",
19     className = "org.apache.derby.jdbc.ClientDataSource",
20     url = "jdbc:derby://localhost:1527/reservation",
21     databaseName = "reservation",
22     user = "APP",
23     password = "APP")
24

60         return true;
61     }
62
63     return false;
64 }
65 catch (SQLException e)
66 {
67     e.printStackTrace();
68     return false;
69 }
70 catch (Exception e)
71 {
72     e.printStackTrace();
73     return false;
74 }
75 finally
76 {
77     try
78     {
79         lookupSeat.close();
80         reserveSeat.close();
81         connection.close();
82     }
83     catch (Exception e)
84     {
85         e.printStackTrace();
86         return false;
87     }
88 }
89 }
90 }
```

Fig. 32.20 | Airline reservation web service. (Part 3 of 3.)

The airline reservation web service has a single web method—`reserve` (lines 33–89)—which searches the `Seats` table to locate a seat matching a user's request. The method takes two arguments—a `String` representing the desired seat type (i.e., "Window", "Middle" or "Aisle") and a `String` representing the desired class type (i.e., "Economy" or "First"). If it finds an appropriate seat, method `reserve` updates the database to make the reservation and returns `true`; otherwise, no reservation is made, and the method returns `false`. The statements at lines 45–50 and lines 56–59 that query and update the database use objects of JDBC types `ResultSet` and `PreparedStatement`.

Software Engineering Observation 32.1

Using `PreparedStatement` to create SQL statements is highly recommended to secure against so-called SQL injection attacks in which executable code is inserted into SQL code. The site www.owasp.org/index.php/Preventing_SQL_Injection_in_Java provides a summary of SQL injection attacks and ways to mitigate against them.

32.10 Consuming a Database-Driven SOAP Web Service 32_45

Our database contains four columns—the seat number (i.e., 1–10), the seat type (i.e., Window, Middle or Aisle), the class type (i.e., Economy or First) and a column containing either 1 (true) or 0 (false) to indicate whether the seat is taken. Lines 45–50 retrieve the seat numbers of any available seats matching the requested seat and class type. This statement fills the `resultSet` with the results of the query

```
SELECT number
  FROM seats
 WHERE (taken = 0) AND (type = type) AND (class = class)
```

The parameters `type` and `class` in the query are replaced with values of method `reserve`'s `seatType` and `classType` parameters.

If `resultSet` is not empty (i.e., at least one seat is available that matches the selected criteria), the condition in line 53 is `true` and the web service reserves the first matching seat number. Recall that `ResultSet` method `next` returns `true` if a nonempty row exists, and positions the cursor on that row. We obtain the seat number (line 55) by accessing `resultSet`'s first column (i.e., `resultSet.getInt(1)`—the first column in the row). Then lines 56–59 configure a `PreparedStatement` and execute the SQL:

```
UPDATE seats
SET taken = 1
WHERE (number = number)
```

which marks the seat as taken in the database. The parameter `number` is replaced with the value of `seat`. Method `reserve` returns `true` (line 60) to indicate that the reservation was successful. If there are no matching seats, or if an exception occurred, method `reserve` returns `false` (lines 63, 68, 73 and 86) to indicate that no seats matched the user's request.

32.10.2 Creating a Web Application to Interact with the Reservation Service

This section presents a `ReservationClient` JSF web application that consumes the `Reservation` web service. The application allows users to select "Aisle", "Middle" or "Window" seats in "Economy" or "First" class, then submit their requests to the web service. If the database request is not successful, the application instructs the user to modify the request and try again. The application presented here was built using the techniques presented in Chapters 30–31. We assume that you've already read those chapters and thus know how to build a Facelets page and a corresponding JavaBean.

index.xhtml

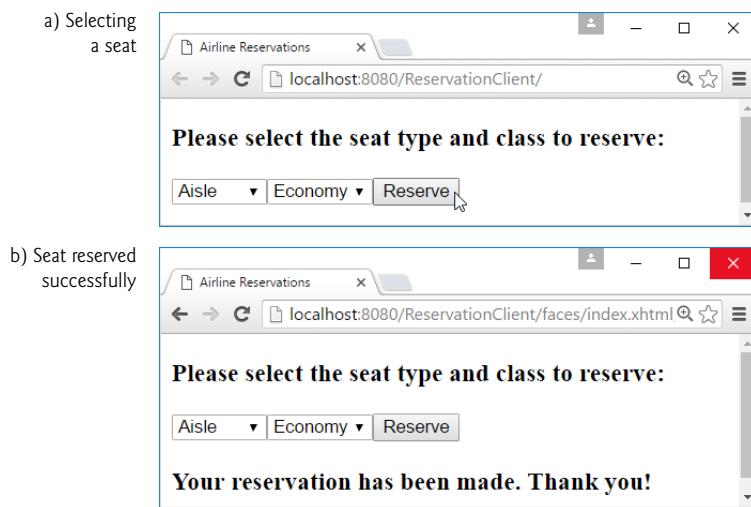

`index.xhtml` (Fig. 32.21) defines two `h:selectOneMenu` and an `h:commandButton`. The `h:selectOneMenu` at lines 16–20) displays all the seat types from which users can select. The one at lines 21–24) provides choices for the class type. The values of these are stored in the `seatType` and `classType` properties of the `reservationBean` (Fig. 32.22). Users click the **Reserve** button (lines 25–26) to submit requests after making selections from the `h:selectOneMenu`s. Clicking the button calls the `reservationBean`'s `reserveSeat` method. The page displays the result of each attempt to reserve a seat in line 28.

c) Attempting to reserve an aisle economy seat when no more are available—because no seats match the requested seat type and class, the user is asked to try again

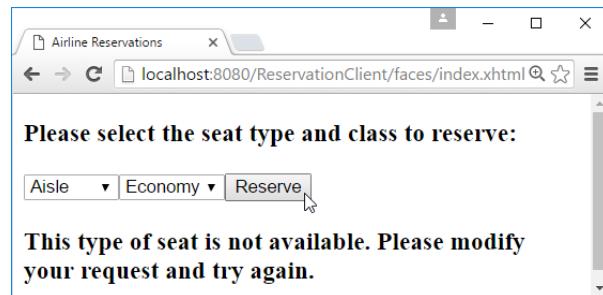

Fig. 32.21 | Facelets page that allows a user to select a seat. (Part 2 of 2.)

ReservationBean.java

Class **ReservationBean** (Fig. 32.22) defines the **seatType**, **classType** and **result** properties and the **reserveSeat** method that are used in the **index.xhtml** page. When the user clicks the **Reserve** button in **index.xhtml**, method **reserveSeat** (lines 59–76) executes. Lines 63–64 use the service endpoint interface object (created in lines 24–25) to invoke the web service’s **reserve** method, passing the selected seat type and class type as arguments. If **reserve** returns **true**, line 67 sets **result** to a message thanking the user for making a reservation; otherwise, lines 69–70 set **result** to a message notifying the user that the requested seat type is not available and instructing the user to try again.

32.11 Equation Generator: Returning User-Defined Types

32_49

32.11 Equation Generator: Returning User-Defined Types

Most of the web services we've demonstrated received and returned primitive-type instances. It's also possible to process instances of class types in a web service. These types can be passed to or returned from web service methods.

This section presents a RESTful `EquationGenerator` web service that generates random arithmetic equations of type `Equation`. The client is a math-tutoring application that accepts information about the mathematical question that the user wishes to attempt (addition, subtraction or multiplication) and the skill level of the user (1 specifies equations using numbers from 1 through 9, 2 specifies equations involving numbers from 10 through 99, and 3 specifies equations containing numbers from 100 through 999). Each web service then generates an equation consisting of random numbers in the proper range. The client application receives the `Equation` and displays the sample question to the user. We present the web service and client twice—once using XML and once using JSON.

Defining Class Equation

We define class `Equation` in Fig. 32.23. All the programs in this section have a copy of this class in their corresponding package. Except for the package name, the class is identical in each project, so we show it only once. Like the `TextMessage` class used earlier, the server-side and client-side copies of class `Equation` are unrelated to each other. The only requirement for *serialization* and *deserialization* to work with the JAXB and Gson classes is that class `Equation` must have the same `public` properties on both the server and the client. Such properties can be `public` instance variables or `private` instance variables that have corresponding, appropriately named `set` and `get` methods.

```

1 // Fig. 32.23: Equation.java
2 // Equation class that contains information about an equation.
3 package com.deitel.equationgeneratorxml;
4
5 public class Equation
6 {
7     private int leftOperand;
8     private int rightOperand;
9     private int result;
10    private String operationType;
11
12    // required no-argument constructor
13    public Equation()
14    {
15        this(0, 0, "add");
16    }
17
18    // constructor that receives the operands and operation type
19    public Equation(int leftValue, int rightValue, String type)
20    {
21        leftOperand = leftValue;
22        rightOperand = rightValue;
23    }

```

32_50 Chapter 32 REST Web Services

```

24      // determine result
25      if (type.equals("add")) // addition
26      {
27          result = leftOperand + rightOperand;
28          operationType = "+";
29      }
30      else if (type.equals("subtract")) // subtraction
31      {
32          result = leftOperand - rightOperand;
33          operationType = "-";
34      }
35      else // multiplication
36      {
37          result = leftOperand * rightOperand;
38          operationType = "*";
39      }
40  }
41
42  // gets the leftOperand
43  public int getLeftOperand()
44  {
45      return leftOperand;
46  }
47
48  // required setter
49  public void setLeftOperand(int value)
50  {
51      leftOperand = value;
52  }
53

55  public int getRightOperand()
56  {
57      return rightOperand;
58  }
59
60  // required setter
61  public void setRightOperand(int value)
62  {
63      rightOperand = value;
64  }
65
66  // gets the resultValue
67  public int getResult()
68  {
69      return result;
70  }
71
72  // required setter
73  public void setResult(int value)
74  {
75      result = value;
76  }

```

Fig. 32.23 | Equation class that contains information about an equation. (Part 2 of 3.)

```

77
78     // gets the operationType
79     public String getOperationType()
80     {
81         return operationType;
82     }
83
84     // required setter
85     public void setOperationType(String value)
86     {
87         operationType = value;
88     }
89
90     // returns the left hand side of the equation as a String
91     public String getLeftHandSide()
92     {
93         return leftOperand + " " + operationType + " " + rightOperand;
94     }
95
96     // returns the right hand side of the equation as a String
97     public String getRightHandSide()
98     {
99         return "" + result;
100    }
101
102    // returns a String representation of an Equation
103    public String toString()
104    {
105        return getLeftHandSide() + " = " + getRightHandSide();
106    }
107 }

```

Fig. 32.23 | Equation class that contains information about an equation. (Part 3 of 3.)

Lines 19–40 define a constructor that takes two `ints` representing the left and right operands, and a `String` representing the arithmetic operation. The constructor stores this information, then calculates the result. The parameterless constructor (lines 13–16) calls the three-argument constructor (lines 19–40) and passes default values.

Class `Equation` defines `get` and `set` methods for example variables `leftOperand` (lines 43–52), `rightOperand` (lines 55–64), `result` (line 67–76) and `operationType` (lines 79–88). It also provides `get` methods for the left-hand and right-hand sides of the equation and a `toString` method that returns the entire equation as a `String`. An instance variable can be serialized only if it has both a `get` and a `set` method. Because the different sides of the equation and the result of `toString` can be generated from the other instance variables, there's no need to send them across the wire. The client in this case study does not use the `getRightHandSide` method, but we included it in case future clients choose to use it.

32.11.1 Creating the EquationGeneratorXML Web Service

Figure 32.24 presents the `EquationGeneratorXML` web service's class for creating randomly generated Equations. Method `getXml` (lines 19–38) takes two parameters—a `String` representing the mathematical operation ("add", "subtract" or "multiply") and an `int`

32.52 Chapter 32 REST Web Services

representing the difficulty level. JAX-RS automatically converts the arguments to the correct type and will return a “not found” error to the client if the argument cannot be converted from a `String` to the destination type. Supported types for conversion include integer types, floating-point types, `boolean` and the corresponding type-wrapper classes.

```

1 // Fig. 32.24: EquationGeneratorXMLResource.java
2 // RESTful equation generator that returns XML.
3 package com.deitel.equationgeneratorxml;
4
5 import java.io.StringWriter;
6 import java.security.SecureRandom;
7 import javax.ws.rs.PathParam;
8 import javax.ws.rs.Path;
9 import javax.ws.rs.GET;
10 import javax.ws.rs.Produces;
11 import javax.xml.bind.JAXB; // utility class for common JAXB operations
12
13 @Path("equation")
14 public class EquationGeneratorXMLResource
15 {
16     private static SecureRandom randomObject = new SecureRandom();
17
18     // retrieve an equation formatted as XML
19     @GET
20     @Path("{operation}/{level}")
21     @Produces("application/xml")
22     public String getXml(@PathParam("operation") String operation,
23                          @PathParam("Level") int level)
24     {
25         // compute minimum and maximum values for the numbers
26         int minimum = (int) Math.pow(10, level - 1);
27         int maximum = (int) Math.pow(10, level);
28
29         // create the numbers on the left-hand side of the equation
30         int first = randomObject.nextInt(maximum - minimum) + minimum;
31         int second = randomObject.nextInt(maximum - minimum) + minimum;
32
33         // create Equation object and marshal it into XML
34         Equation equation = new Equation(first, second, operation);
35         StringWriter writer = new StringWriter(); // XML output here
36         JAXB.marshal(equation, writer); // write Equation to StringWriter
37         return writer.toString(); // return XML string
38     }
39 }
```

Fig. 32.24 | RESTful equation generator that returns XML.

The `getXml` method first determines the minimum (inclusive) and maximum (exclusive) values for the numbers in the equation it will return (lines 26–27). It then uses a `Random` object (created at line 16) to generate two random numbers in that range (lines 30–31). Line 34 creates an `Equation` object, passing these two numbers and the requested operation to the constructor. The `getXml` method then uses JAXB to convert the `Equation` object to XML (line 36), which is output to the `StringWriter` created on line 35. Finally,

it retrieves the data that was written to the `StringWriter` and returns it to the client. For example, if you invoke the web service with

```
http://localhost:8080/EquationGeneratorXML/webresources/equation/
add/1
```

the response will have the format

```
<equation>
<leftOperand>6</leftOperand>
<operationType>+</operationType>
<result>11</result>
<rightOperand>5</rightOperand>
</equation>
```

[Note: We'll reimplement this web service with JSON in Section 32.11.3.]

32.11.2 Consuming the EquationGeneratorXML Web Service

The `EquationGeneratorXMLClient` application (Fig. 32.25) retrieves an XML-formatted `Equation` object from the `EquationGeneratorXML` web service. The application then displays the `Equation`'s left-hand side and waits for user to submit an answer.

```

1 // Fig. 32.25: EquationGeneratorXMLClientJFrame.java
2 // Math-tutoring program using REST and XML to generate equations.
3 package com.deitel.equationgeneratorxmlclient;
4
5 import javax.swing.JOptionPane;
6 import javax.xml.bind.JAXB; // utility class for common JAXB operations
7
8 public class EquationGeneratorXMLClientJFrame extends javax.swing.JFrame
9 {
10    private String operation = "add"; // operation user is tested on
11    private int difficulty = 1; // 1, 2, or 3 digits in each number
12    private int answer; // correct answer to the question
13
14    // no-argument constructor
15    public EquationGeneratorXMLClientJFrame()
16    {
17        initComponents();
18    }
19
20    // The initComponents method is autogenerated by NetBeans and is called
21    // from the constructor to initialize the GUI. This method is not shown
22    // here to save space. Open EquationGeneratorXMLClientJFrame.java in
23    // this example's folder to view the complete generated code.
24
25    // determine if the user answered correctly
26    private void checkAnswerJButtonActionPerformed(
27        java.awt.event.ActionEvent evt)
28    {
29        if (answerJTextField.getText().equals(""))
30        {
```

// The initComponents method is autogenerated by NetBeans and is called
// from the constructor to initialize the GUI. This method is not shown
// here to save space. Open EquationGeneratorXMLClientJFrame.java in
// this example's folder to view the complete generated code.

123 }

```

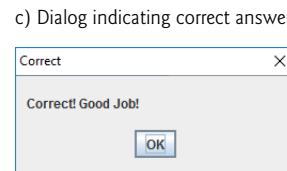

a) Generating a simple equation.

b) Submitting the answer.

c) Dialog indicating correct answer.

**Fig. 32.25** | Math-tutoring program using REST and XML to generate equations. (Part 3 of 3.)

32.56 Chapter 32 REST Web Services

The default setting for the difficulty level is 1, but the user can change this by choosing a level from the **Choose level** JComboBox. Changing the selected value invokes the `levelJComboBoxItemStateChanged` event handler (lines 212–217), which sets the `difficulty` instance variable to the level selected by the user. Although the default setting for the question type is **Addition**, the user also can change this by choosing from the **Choose operation** JComboBox. This invokes the `operationJComboBoxItemStateChanged` event handler in lines 198–209, which assigns to instance variable `operation` the String corresponding to the user's selection.

The event handler for `generateJButton` (lines 175–195) constructs the URL to invoke the web service, then passes this URL to the `unmarshal` method, along with an instance of `Class<Equation>`, so that JAXB can convert the XML into an `Equation` object (line 185). Once the XML has been converted back into an `Equation`, lines 183–184 retrieve the correct answer and display the left-hand side of the equation. The **Check Answer** button is then enabled (line 189), and the user must solve the problem and enter the answer.

When the user enters a value and clicks **Check Answer**, the `checkAnswerJButtonActionPerformed` event handler (lines 148–172) retrieves the user's answer from the dialog box (line 157) and compares it to the correct answer that was stored earlier (line 159). If they match, lines 161–165 reset the GUI elements so the user can generate another equation and tell the user that the answer was correct. If they do not match, a message box asking the user to try again is displayed (lines 169–170).

32.11.3 Creating the EquationGeneratorJSON Web Service

As you saw in Section 32.8, RESTful web services can return data formatted as JSON as well. Figure 32.26 is a reimplementation of the `EquationGeneratorXML` service that returns an `Equation` in JSON format. The logic implemented here is the same as the XML version except for the last line (line 34), which uses `Gson` to convert the `Equation` object into JSON instead of using JAXB to convert it into XML. The `@Produces` annotation (line 20) has also changed to reflect the JSON data format.

```

1 // Fig. 32.26: EquationGeneratorJSONResource.java
2 // RESTful equation generator that returns JSON.
3 package com.deitel.equationgeneratorjson;
4
5 import com.google.gson.Gson; // converts POJO to JSON and back again
6 import java.util.Random;
7 import javax.ws.rs.GET;
8 import javax.ws.rs.Path;
9 import javax.ws.rs.PathParam;
10 import javax.ws.rs.Produces;
11
12 @Path("equation")
13 public class EquationGeneratorJSONResource
14 {
15     static Random randomObject = new Random(); // random number generator
16 }
```

Fig. 32.26 | RESTful equation generator that returns JSON. (Part I of 2.)

```

17 // retrieve an equation formatted as JSON
18 @GET
19 @Path("{operation}/{level}")
20 @Produces("application/json")
21 public String getJson(@PathParam("operation") String operation,
22                      @PathParam("level") int level)
23 {
24     // compute minimum and maximum values for the numbers
25     int minimum = (int) Math.pow(10, level - 1);
26     int maximum = (int) Math.pow(10, level);
27
28     // create the numbers on the left-hand side of the equation
29     int first = randomObject.nextInt(maximum - minimum) + minimum;
30     int second = randomObject.nextInt(maximum - minimum) + minimum;
31
32     // create Equation object and return result
33     Equation equation = new Equation(first, second, operation);
34     return new Gson().toJson(equation); // convert to JSON and return
35 }
36 }
```

32.11.4 Consuming the EquationGeneratorJSON Web Service

The program in Fig. 32.27 consumes the `EquationGeneratorJSON` service and performs the same function as `EquationGeneratorXMLClient`—the only difference is in how the `Equation` object is retrieved from the web service. Lines 181–183 construct the URL that is used to invoke the `EquationGeneratorJSON` service. As in the `WelcomeRESTJSONClient` example, we use the `URL` class and an `InputStreamReader` to invoke the web service and read the response (lines 186–187). The retrieved JSON is *deserialized* using `Gson` (line 191) and converted back into an `Equation` object. As before, we use the `getResult` method (line 194) of the deserialized object to obtain the answer and the `getLeftHandSide` method (line 195) to display the left side of the equation.

```

1 // Fig. 32.27: EquationGeneratorJSONClientJFrame.java
2 // Math-tutoring program using REST and JSON to generate equations.
3 package com.deitel.equationgeneratorjsonclient;
4
5 import com.google.gson.Gson; // converts POJO to JSON and back again
6 import java.io.InputStreamReader;
7 import java.net.URL;
8 import javax.swing.JOptionPane;
9
10 public class EquationGeneratorJSONClientJFrame extends javax.swing.JFrame
11 {
12     private String operation = "add"; // operation user is tested on
13     private int difficulty = 1; // 1, 2, or 3 digits in each number
14     private int answer; // correct answer to the question
15 }
```

32.12 Wrap-Up

This chapter introduced web services—a set of technologies for building distributed systems in which system components communicate with one another over networks. In particular, we presented JAX-WS SOAP-based web services and JAX-RS REST-based web services. You learned that a web service is a class that allows client software to call the web service’s methods remotely via common data formats and protocols, such as XML, JSON, HTTP, SOAP and REST. We also benefits of distributed computing with web services.

We explained how NetBeans and the JAX-WS and JAX-RS APIs facilitate publishing and consuming web services. You learned how to define web services and methods using both SOAP protocol and REST architecture, and how to return data in both XML and JSON formats. You consumed SOAP-based web services using proxy classes to call the web service’s methods. You also consumed REST-based web services by using class URL to invoke the services and open `InputStreams` from which the clients could read the services’ responses. You learned how to define web services and web methods, as well as how to consume them both from Java desktop applications and from web applications. After explaining the mechanics of web services through our `Welcome` examples, we demonstrated more sophisticated web services that use session tracking, database access and user-defined types. We also explained XML and JSON serialization and showed how to retrieve objects of user-defined types from web services.

Summary

Section 32.1 Introduction

- A web service (p. 2) is a software component stored on one computer that can be accessed by an application (or other software component) on another computer over a network.
- Web services communicate using such technologies as XML, JSON and HTTP.
- JAX-WS (p. 2) is based on the Simple Object Access Protocol (SOAP; p. 2)—an XML-based protocol that allows web services and clients to communicate.
- JAX-RS (p. 2) uses Representational State Transfer (REST; p. 2)—a network architecture that uses the web’s traditional request/response mechanisms such as `GET` and `POST` requests.
- Web services enable businesses to conduct transactions via standardized, widely available web services rather than relying on proprietary applications.

- Web services are platform and language independent, so companies can collaborate via web services without hardware, software and communications compatibility issues.
- NetBeans is one of the many tools that enable you to publish and/or consume web services.

Section 32.2 Web Service Basics

- The machine on which a web service resides is referred to as a web service host.
- A client application that accesses the web service sends a method call over a network to the web service host, which processes the call and returns a response over the network to the application.
- In Java, a web service is implemented as a class. The class that represents the web service resides on a server—it's not part of the client application.
- Making a web service available to receive client requests is known as publishing a web service (p. 4); using a web service from a client application is known as consuming a web service (p. 4).

Section 32.3 Simple Object Access Protocol (SOAP)

- SOAP is a platform-independent protocol that uses XML to make remote procedure calls, typically over HTTP. Each request and response is packaged in a SOAP message (p. 4)—an XML message containing the information that a web service requires to process the message.
- SOAP messages are written in XML so that they're computer readable, human readable and platform independent.
- SOAP supports an extensive set of types—the primitive types, as well as `DateTime`, `XmlNode` and others. SOAP can also transmit arrays of these types.
- When a program invokes a method of a SOAP web service, the request and all relevant information are packaged in a SOAP message, enclosed in a SOAP envelope (p. 4) and sent to the server on which the web service resides.
- When a web service receives a SOAP message, it parses the XML representing the message, then processes the message's contents. The message specifies the method that the client wishes to execute and the arguments the client passed to that method.
- After a web service parses a SOAP message, it calls the appropriate method with the specified arguments (if any) and sends the response back to the client in another SOAP message. The client parses the response to retrieve the method's result.

Section 32.4 Representational State Transfer (REST)

- Representational State Transfer (REST) refers to an architectural style for implementing web services. Such web services are often called RESTful web services (p. 4). Though REST itself is not a standard, RESTful web services are implemented using web standards.
- Each operation in a RESTful web service is identified by a unique URL.
- REST can return data in many formats, including XML and JSON.

Section 32.5 JavaScript Object Notation (JSON)

- JavaScript Object Notation (JSON; p. 5) is an alternative to XML for representing data.
- JSON is a text-based data-interchange format used to represent objects in JavaScript as collections of name/value pairs represented as `Strings`.
- JSON is a simple format that makes objects easy to read, create and parse and allows programs to transmit data efficiently across the Internet, because it's much less verbose than XML.
- Each value in a JSON array can be a string, a number, a JSON object, `true`, `false` or `null`.

32_62 Chapter 32 REST Web Services

Section 32.6.1 Creating a Web Application Project and Adding a Web Service Class in NetBeans

- When you create a web service in NetBeans, you focus on the web service’s logic and let the IDE handle the web service’s infrastructure.
- To create a web service in NetBeans, you first create a **Web Application** project (p. 5).

Section 31.6.2 Defining the *WelcomeSOAP* Web Service in NetBeans

- By default, each new web service class created with the JAX-WS APIs is a POJO (plain old Java object)—you do not need to extend a class or implement an interface to create a web service.
- When you deploy a web application containing a JAX-WS web service, the server creates the server-side artifacts that support the web service.
- The `@WebService` annotation (p. 7) indicates that a class represents a web service. The optional `name` attribute (p. 7) specifies the service endpoint interface (SEI; p. 7) class’s name. The optional `serviceName` attribute (p. 7) specifies the name of the class that the client uses to obtain an SEI object.
- Methods that are tagged with the `@WebMethod` annotation (p. 7) can be called remotely.
- The `@WebMethod` annotation’s optional `operationName` attribute (p. 7) specifies the method name that is exposed to the web service’s clients.
- Web method parameters are annotated with the `@WebParam` annotation (p. 8). The optional `name` attribute (p. 8) indicates the parameter name that is exposed to the web service’s clients.

Section 31.6.3 Publishing the *WelcomeSOAP* Web Service from NetBeans

- NetBeans handles all the details of building and deploying a web service for you. This includes creating the framework required to support the web service.

Section 31.6.4 Testing the *WelcomeSOAP* Web Service with GlassFish Application Server’s Tester Web Page

- GlassFish can dynamically create a web page for testing a web service’s methods from a web browser. To open the test page, expand the project’s **Web Services** node in the NetBeans **Projects** tab, then right click the web service class name and select **Test Web Service**.
- A client can access a web service only when the application server is running. If NetBeans launches the application server for you, the server will shut down when you close NetBeans. To keep the application server up and running, you can launch it independently of NetBeans.

Section 32.6.5 Describing a Web Service with the Web Service Description Language (WSDL)

- To consume a web service, a client must know where to find it and must be provided with the web service’s description.
- JAX-WS uses the Web Service Description Language (WSDL; p. 11)—a standard XML vocabulary for describing web services in a platform-independent manner.
- The server generates a web service’s WSDL dynamically for you, and client tools can parse the WSDL to help create the client-side proxy class that a client uses to access the web service.

Section 31.6.6 Creating a Client to Consume the *WelcomeSOAP* Web Service

- A web service reference (p. 12) defines the service endpoint interface class so that a client can access the a service.

- An application that consumes a SOAP-based web service invokes methods on a service endpoint interface (SEI) object that interact with the web service on the client's behalf.
- The service endpoint interface object handles the details of passing method arguments to and receiving return values from the web service. This communication can occur over a local network, over the Internet or even with a web service on the same computer.
- NetBeans creates these service endpoint interface classes for you.
- When you add the web service reference, the IDE creates and compiles the client-side artifacts—the framework of Java code that supports the client-side service endpoint interface class. The service endpoint interface class uses the rest of the artifacts to interact with the web service.
- A web service reference is added by giving NetBeans the URL of the web service's WSDL file.

Section 31.6.7 Consuming the WelcomeSOAP Web Service

- To consume a JAX-WS web service, you must obtain an SEI object. You then invoke the web service's methods through the SEI object.

Section 32.7.1 Creating a REST-Based XML Web Service

- The **RESTful Web Services** plug-in for NetBeans provides various templates for creating RESTful web services, including ones that can interact with databases on the client's behalf.
- The `@Path` annotation (p. 17) on a JAX-RS web service class indicates the URI for accessing the web service. This is appended to the web application project's URL to invoke the service. Methods of the class can also use the `@Path` annotation.
- Parts of the path specified in curly braces indicate parameters—they're placeholders for arguments that are passed to the web service as part of the path. The base path for the service is the project's `resources` directory.
- Arguments in a URL can be used as arguments to a web service method. To do so, you bind the parameters specified in the `@Path` specification to parameters of a web service method with the `@PathParam` annotation (p. 19). When the request is received, the server passes the argument(s) in the URL to the appropriate parameter(s) in the web service method.
- The `@GET` annotation (p. 19) denotes that a method is accessed via an HTTP GET request. Similar annotations exist for HTTP PUT, POST, DELETE and HEAD requests.
- The `@Produces` annotation (p. 19) denotes the content type returned to the client. It's possible to have multiple methods with the same HTTP method and path but different `@Produces` annotations, and JAX-RS will call the method matching the content type requested by the client.
- The `@Consumes` annotation (p. 19) restricts the content type that a web service accepts from a PUT request.
- JAXB (Java Architecture for XML Binding; p. 19) is a set of classes for converting POJOs to and from XML. Class `JAXB` (package `javax.xml.bind`) contains static methods for common operations.
- Class `JAXB`'s static method `marshal` (p. 19) converts a Java object to XML format.
- WADL (Web Application Description Language; p. 20) has similar design goals to WSDL, but describes RESTful services instead of SOAP services.

Section 32.7.2 Consuming a REST-Based XML Web Service

- Clients of RESTful web services do not require web service references.
- The `JAXB` class has a static `unmarshal` method that takes as arguments a filename or URL as a `String`, and a `Class<T>` object indicating the Java class to which the XML will be converted.

32_64 Chapter 32 REST Web Services

Section 32.8 Publishing and Consuming REST-Based JSON Web Services

- JSON components—objects, arrays, strings, numbers—can be easily mapped to constructs in Java and other programming languages.

Section 32.8.1 Creating a REST-Based JSON Web Service

- To add a JAR file as a library in NetBeans, right click your project's **Libraries** folder, select **Add JAR/Folder...**, locate the JAR file and click **Open**.
- For a web service method that returns JSON text, the argument to the `@Produces` attribute must be "application/json".
- In JSON, all data must be encapsulated in a composite data type.
- Create a `Gson` object (from package `com.google.gson`) and call its `toJson` method to convert an object into its JSON String representation.

Section 32.8.2 Consuming a REST-Based JSON Web Service

- To read JSON data from a URL, create a `URL` object and call its `openStream` method (p. 26). This invokes the web service and returns an `InputStream` from which the client can read the response. Wrap the `InputStream` in an `InputStreamReader` so it can be passed as the first argument to the `Gson` class's `fromJson` method (p. 26).

Section 32.9 Session Tracking in a SOAP Web Service

- It can be beneficial for a web service to maintain client state information, thus eliminating the need to pass client information between the client and the web service multiple times. Storing session information also enables a web service to distinguish between clients.

Section 31.9.1 Creating a Blackjack Web Service

- In JAX-WS 2.2, to enable session tracking in a web service, you simply precede your web service class with the `@HttpSessionScope` annotation (p. 29) from package `com.sun.xml.ws.developer.servlet`. To use this package you must add the JAX-WS 2.2 library to your project.
- Once a web service is annotated with `@HttpSessionScope`, the server automatically maintains a separate instance of the class for each client session.

Section 31.9.2 Consuming the Blackjack Web Service

- In the JAX-WS framework, the client must indicate whether it wants to allow the web service to maintain session information. To do this, first cast the proxy object to interface type `BindingProvider`. A `BindingProvider` enables the client to manipulate the request information that will be sent to the server. This information is stored in an object that implements interface `RequestContext`. The `BindingProvider` and `RequestContext` are part of the framework that is created by the IDE when you add a web service client to the application.
- Next, invoke the `BindingProvider`'s `getRequestContext` method to obtain the `RequestContext` object. Then call the `RequestContext`'s `put` method to set the property `BindingProvider.SESSION_MAINTAIN_PROPERTY` to `true`, which enables session tracking from the client side so that the web service knows which client is invoking the service's web methods.

Section 32.11 Equation Generator: Returning User-Defined Types

- It's also possible to process instances of class types in a web service. These types can be passed to or returned from web service methods.
- An instance variable can be serialized only if it's `public` or has both a `get` and a `set` method.

Self-Review Exercises 32-65

- Properties that can be generated from the values of other properties should not be serialized to prevent redundancy.
- JAX-RS automatically converts arguments from an `@Path` annotation to the correct type, and it will return a “not found” error to the client if the argument cannot be converted from the `String` passed as part of the URL to the destination type. Supported types for conversion include integer types, floating-point types, `boolean` and the corresponding type-wrapper classes.

Self-Review Exercises

32.1 State whether each of the following is *true* or *false*. If *false*, explain why.

- a) All methods of a web service class can be invoked by clients of that web service.
- b) When consuming a web service in a client application created in NetBeans, you must create the proxy class that enables the client to communicate with the web service.
- c) A proxy class communicating with a web service normally uses SOAP to send and receive messages.
- d) Session tracking is automatically enabled in a client of a web service.
- e) Web methods cannot be declared `static`.
- f) A user-defined type used in a web service must define both `get` and `set` methods for any property that will be serialized.
- g) Operations in a REST web service are defined by their own unique URLs.
- h) A SOAP-based web service can return data in JSON format.

32.2 Fill in the blanks for each of the following statements:

- a) A key difference between SOAP and REST is that SOAP messages have data wrapped in a(n) _____.
- b) A web service in Java is a(n) _____—it does not need to implement any interfaces or extend any classes.
- c) Web service requests are typically transported over the Internet via the _____ protocol.
- d) To set the exposed name of a web method, use the _____ element of the `@WebMethod` annotation.
- e) _____ transforms an object into a format that can be sent between a web service and a client.
- f) To return data in JSON format from a method of a REST-based web service, the `@Produces` annotation is set to _____.
- g) To return data in XML format from a method of a REST-based web service, the `@Produces` annotation is set to _____.

Answers to Self-Review Exercises

32.1 a) False. Only methods declared with the `@WebMethod` annotation can be invoked by a web service’s clients. b) False. The proxy class is created by NetBeans when you add a web service client to the application. c) True. d) False. In the JAX-WS framework, the client must indicate whether it wants to allow the web service to maintain session information. First, you must cast the proxy object to interface type `BindingProvider`, then use the `BindingProvider`’s `getRequestContext` method to obtain the `RequestContext` object. Finally, you must use the `RequestContext`’s `put` method to set the property `BindingProvider.SESSION_MAINTAIN_PROPERTY` to `true`. e) True. f) True. g) True. h) False. A SOAP web service implicitly returns data in XML format.

32.2 a) SOAP message or SOAP envelope. b) POJO (plain old Java object) c) HTTP. d) `operationName`. e) serialization. f) "application/json". g) "application/xml".

32_66 Chapter 32 REST Web Services

Exercises

32.3 (Phone Book Web Service) Create a RESTful web service that stores phone book entries in the database PhoneBookDB and a web client application that consumes this service. The web service should output XML. Use the steps in Section 31.2.1 to create the PhoneBook database and a data source name for accessing it. The database contains one table—PhoneBook—with three columns—LastName, FirstName and PhoneNumber. The LastName and FirstName columns store up to 30 characters. The PhoneNumber column supports phone numbers of the form (800) 555-1212 that contain 14 characters. Use the PhoneBookDB.sql script provided in the examples folder to create the PhoneBook table.

Give the client user the capability to enter a new contact (web method addEntry) and to find contacts by last name (web method getEntries). Pass only Strings as arguments to the web service. The getEntries web method should return an array of Strings that contains the matching phone book entries. Each String in the array should consist of the last name, first name and phone number for one phone book entry. These values should be separated by commas.

The SELECT query that will find a PhoneBook entry by last name should be:

```
SELECT LastName, FirstName, PhoneNumber
FROM PhoneBook
WHERE (LastName = LastName)
```

The INSERT statement that inserts a new entry into the PhoneBook database should be:

```
INSERT INTO PhoneBook (LastName, FirstName, PhoneNumber)
VALUES (LastName, FirstName, PhoneNumber)
```

32.4 (Phone Book Web Service Modification) Modify Exercise 32.3 so that it uses a class named PhoneBookEntry to represent a row in the database. The web service should return objects of type PhoneBookEntry in XML format for the getEntries method, and the client application should use the JAXB method unmarshal to retrieve the PhoneBookEntry objects.

32.5 (Phone-Book Web Service with JSON) Modify Exercise 32.4 so that the PhoneBookEntry class is passed to and from the web service as a JSON object. Use serialization to convert the JSON object into an object of type PhoneBookEntry.

32.6 (Blackjack Web Service Modification) Modify the Blackjack web service example in Section 32.9 to include class Card. Modify web method dealCard so that it returns an object of type Card and modify web method getHandValue so that it receives an array of Card objects from the client. Also modify the client application to keep track of what cards have been dealt by using ArrayLists of Card objects. The proxy class created by NetBeans will treat a web method's array parameter as a List, so you can pass these ArrayLists of Card objects directly to the getHandValue method. Your Card class should include set and get methods for the face and suit of the card.

32.7 (Project: Airline Reservation Web-Service Modification) Modify the airline reservation web service in Section 32.10 so that it contains two separate methods—one that allows users to view all available seats, and another that allows users to reserve a particular seat that is currently available. Use an object of type Ticket to pass information to and from the web service. The web service must be able to handle cases in which two users view available seats, one reserves a seat and the second user tries to reserve the same seat, not knowing that it's now taken. The names of the methods that execute should be reserve and getAllAvailableSeats.

32.8 (Project: Morse Code Web Service) In Exercise 14.22, you learned about Morse Code and wrote applications that could translate English phrases into Morse Code and vice versa. Create a SOAP-based web service that provides two methods—one that translates an English phrase into

Morse Code and one that translates Morse Code into English. Next, build a Morse Code translator GUI application that invokes the web service to perform these translations.

Making a Difference

32.9 (*Project: Spam Scanner Web Service*) In Exercise 14.27, you created a spam scanner application that scanned an e-mail and gave it a point rating based on the occurrence of certain words and phrases that commonly appear in spam e-mails and how many times the words and phrases occurred in the e-mail. Create a SOAP-based Spam scanner web service. Next, modify the GUI application you created in Exercise 14.27 to use the web service to scan an e-mail. Then display the point rating returned by the web service.

32.10 (*Project: SMS Web Service*) In Exercise 14.28, you created an SMS message-translator application. Create a SOAP-based web service with three methods:

- a) one that receives an SMS abbreviation and returns the corresponding English word or phrase,
- b) one that receives an entire SMS message and returns the corresponding English text, and
- c) one that translates English text into an SMS message.

Use the web service from a GUI application that displays the web service's responses.

32.11 (*Project: Gender-Neutrality Web Service*) In Exercise 1.12, you researched eliminating sexism in all forms of communication. You then described the algorithm you'd use to read through a paragraph of text and replace gender-specific words with gender-neutral equivalents. Create a SOAP-based web service that receives a paragraph of text, then replaces gender-specific words with gender-neutral ones. Use the web service from a GUI application that displays the resulting gender-neutral text.
